

LARGE SYSTEMS OF PATH-REPELLENT BROWNIAN MOTIONS IN A TRAP AT POSITIVE TEMPERATURE

BY STEFAN ADAMS¹, JEAN-BERNARD BRU² AND WOLFGANG KÖNIG³

(2 May 2006)

Abstract: We study a model of N mutually repellent Brownian motions under confinement to stay in some bounded region of space. Our model is defined in terms of a transformed path measure under a trap Hamiltonian, which prevents the motions from escaping to infinity, and a pair-interaction Hamiltonian, which imposes a repellency of the N paths. In fact, this interaction is an N -dependent regularisation of the Brownian intersection local times, an object which is of independent interest in the theory of stochastic processes.

The time horizon (interpreted as the inverse temperature) is kept fixed. We analyse the model for diverging number of Brownian motions in terms of a large deviation principle. The resulting variational formula is the positive-temperature analogue of the well-known Gross-Pitaevskii formula, which approximates the ground state of a certain dilute large quantum system; the kinetic energy term of that formula is replaced by a probabilistic energy functional.

This study is a continuation of the analysis in [ABK06] where we considered the limit of diverging time (i.e., the zero-temperature limit) with fixed number of Brownian motions, followed by the limit for diverging number of motions.

1. INTRODUCTION AND MAIN RESULTS

1.1 Introduction.

We make a contribution to a rigorous analysis of a certain model of a large number of mutually repellent Brownian motions with a fixed finite time horizon in a trap. The pair interaction induces a repellency between each pair of paths. More precisely, it is an approximation of a highly irregular functional of the motions, the so-called *Brownian intersection local times*, which measure the amount of time that is spent by two motions at their intersection points. Since the intersection local times are non-trivial only in dimensions $d = 2$ and $d = 3$, the present paper is naturally restricted to these dimensions. Our main result is a large deviation principle for the mean of regularisations of the intersection local times, taken over all mutual intersections of a large number of Brownian paths. The rate function has three terms: the Legendre-Fenchel transform of the logarithmic moment generating function for the normalised occupation measure of one of the motions, a trap term and a quartic term, expressing the limiting effective interaction. This rate function can be seen as the finite-time version of the well-known *Gross-Pitaevskii energy function*, see (1.15) below. The only difference is the energy term, which is replaced by the Legendre-Fenchel transform in our result. Hence, this transform gains the interpretation of a *probabilistic energy functional*.

We introduced this model in earlier work [ABK06]. It turned out there that its behaviour in the large-time limit is asymptotically well described by a variational formula known as the *Hartree formula*. Therefore, we call this model the *Hartree model*. The interaction Hamiltonian is given via a double time integration and thus the Hartree model is related to Polaron type models [DV83], [BDS93], where instead of several paths a single path is considered. Our main motivation, however, stems from certain questions in quantum statistical mechanics, see Section 1.4 below. One important open problem is the description of the large- N behaviour of the trace of $e^{-\beta H_N}$ for fixed positive inverse temperature β , where H_N is the Hamilton operator for N mutually repellent particles in a trap. Via the Feynman-Kac formula, this trace is expressed in terms of a Brownian motion model on the time interval $[0, \beta]$ that is in the spirit of the model considered in the present paper. The main difference, however, is that the interaction in the trace formula is a *particle* interaction, while the Hartree model has a *path* interaction. We consider the successful analysis of the Hartree model as an instructive step towards an understanding of the trace formula.

In this paper, we consider large- N limits only for systems that are dilute on a particular scale. This scale is determined by the requirement that all the three components (energy, trap, interaction) give nontrivial contributions and that the system occupies a region in space that does not depend on N . Therefore, we pick the interaction range as $1/N$, and its strength as N^{d-1} , see (1.4). For $d = 3$, this is the scale on which Lieb *et al.* [LSSY05] analysed the ground state (i.e., $\beta = \infty$) of the above mentioned Hamilton operator and showed that its large- N behaviour is well approximated by the Gross-Pitaevskii formula. By rescaling, this corresponds to a large system with constant interaction and a trap growing with N in such a way that the particle density shrinks like $1/N^2$. The interaction potential enters the Gross-Pitaevskii formula only via its scattering length as a prefactor of the quartic term.

In [ABK06] we showed that the many-particle limit of the Hartree formula, which describes the large-time limit of the Hartree model, is also well approximated by the Gross-Pitaevskii formula. However, the decisive parameter here is not the scattering length, but the *integral* of the pair interaction functional. While that result describes the zero-temperature situation, in the present work we study the case of *positive* temperature, i.e., interacting Brownian motions on a fixed *finite* time horizon, in the limit of many particles.

The remainder of Section 1 is organised as follows. We introduce the model in Section 1.2 and present our main result and some conclusions in Section 1.3. In Section 1.4 we embed these results in a broader perspective, discuss our results and mention some open problems.

The remainder of the paper is structured as follows. In Section 2 we prove some properties of the probabilistic energy term and the variational formula. Section 3 contains the proof of our main result. In the Appendix we give a short account on large deviation theory in Section 4.1 and recall a related result by Lieb *et al.* on the large- N limit of the ground state in Section 4.2.

1.2 The model.

We consider a family of N independent Brownian motions, $(B_t^{(1)})_{t \geq 0}, \dots, (B_t^{(N)})_{t \geq 0}$, in \mathbb{R}^d with generator Δ each. We assume that each motion possesses the same initial distribution, which we do not want to make explicit. The model we study is defined in terms of a Hamiltonian which consists of two parts: a trap part,

$$H_{N,\beta} = \sum_{i=1}^N \int_0^\beta W(B_s^{(i)}) ds, \quad (1.1)$$

and a pair-interaction part,

$$K_{N,\beta} = \sum_{1 \leq i < j \leq N} \frac{1}{\beta} \int_0^\beta \int_0^\beta v(|B_s^{(i)} - B_t^{(j)}|) ds dt. \quad (1.2)$$

Here $W: \mathbb{R}^d \rightarrow [0, \infty]$ is the so-called *trap potential* satisfying $\lim_{|x| \rightarrow \infty} W(x) = \infty$, and $v: (0, \infty) \rightarrow [0, \infty]$ is a pair-interaction function satisfying $0 < \lim_{r \downarrow 0} v(r) \leq \infty$ and $\int_{\mathbb{R}^d} v(|x|) dx < \infty$. We are interested in the large- N behaviour of the transformed path measure,

$$e^{-H_{N,\beta} - K_{N,\beta}} d\mathbb{P}. \quad (1.3)$$

Here $\beta \in (0, \infty)$ is a finite time horizon which we will keep fixed in this paper. The trap part effectively keeps the motions in a bounded region of the space \mathbb{R}^d . Through the pair interaction $K_{N,\beta}$, the i -th Brownian motion interacts with the mean of the whole path of the j -th motion, taken over all times before β . Hence, the interaction is not a *particle* interaction, but a *path* interaction. We are most interested in the case $\lim_{r \downarrow 0} v(r) = \infty$, where the pair-interaction repels all the motions from each other (more precisely, their paths). In order to keep the notation simpler, we abstained from normalising the path measure in (1.3).

The model in (1.3) was introduced and studied in [ABK06]; see Section 1.4 for results from that paper and a discussion of the physical relevance of the model. In particular, in the limit $\beta \rightarrow \infty$, followed by $N \rightarrow \infty$, a certain variational formula appears that is called the *Hartree formula* in the literature. Therefore, we call the model in (1.3) the *Hartree model*.

When we take the limit as $N \rightarrow \infty$, we will not keep the pair-interaction function v fixed, but we replace it by the rescaled version $v_N(\cdot) = N^{d-1}v(N \cdot)$. In other words, we replace $K_{N,\beta}$ with

$$K_{N,\beta}^{(N)} = \frac{1}{N} \sum_{1 \leq i < j \leq N} \frac{1}{\beta} \int_0^\beta \int_0^\beta N^d v(N|B_s^{(i)} - B_t^{(j)}|) ds dt. \quad (1.4)$$

Note that $N^d v(N \cdot)$ is an approximation of the Dirac measure at zero times the integral of $v \circ |\cdot|$, hence the double integral in (1.4) is an approximation of the *Brownian intersection local times* at zero, an important object in the present paper. The Brownian intersection local times measure the time spent by two motions on the intersection of their paths, see Section 3.1. A natural sense can be given to this object only in dimensions $d \in \{2, 3\}$. Therefore, our analysis is naturally restricted to these dimensions. The main difficulty in the analysis of the model will stem from the N -dependence and the high irregularity of the pair-interaction part.

1.3 Results.

We now formulate our results on the behaviour of the Hartree model in the limit as $N \rightarrow \infty$, with $\beta > 0$ fixed. First we introduce an important functional, which will play the role of a probabilistic energy functional. Define $J_\beta: \mathcal{M}_1(\mathbb{R}^d) \rightarrow [0, \infty]$ as the Legendre-Fenchel transform of the map $\mathcal{C}_b(\mathbb{R}^d) \ni f \mapsto \frac{1}{\beta} \log \mathbb{E}[e^{\int_0^\beta f(B_s) ds}]$ on the set $\mathcal{C}_b(\mathbb{R}^d)$ of continuous bounded functions on \mathbb{R}^d , where $(B_s)_{s \geq 0}$ is one of the above Brownian motions. That is,

$$J_\beta(\mu) = \sup_{f \in \mathcal{C}_b(\mathbb{R}^d)} \left(\langle \mu, f \rangle - \frac{1}{\beta} \log \mathbb{E}[e^{\int_0^\beta f(B_s) ds}] \right), \quad \mu \in \mathcal{M}_1(\mathbb{R}^d). \quad (1.5)$$

Here $\mathcal{M}_1(\mathbb{R}^d)$ denotes the set of probability measures on \mathbb{R}^d . Note that J_β depends on the initial distribution of the Brownian motion. In Lemma 2.1 below we show that J_β is not identical to $+\infty$. Alternate expressions for J_β are given in Lemma 2.3 below. Clearly, J_β is a lower semi continuous and convex functional on $\mathcal{M}_1(\mathbb{R}^d)$, which we endow with the topology of weak convergence induced by test integrals against continuous bounded functions. However, J_β is *not* a quadratic form coming from any linear operator. We wrote $\langle \mu, f \rangle = \int_{\mathbb{R}^d} f(x) \mu(dx)$ and use also the notation $\langle f, g \rangle = \int_{\mathbb{R}^d} f(x)g(x) dx$ for integrable functions f, g . If μ possesses a Lebesgue density ϕ^2 for some L^2 -normalised $\phi \in L^2$, then we also write $J_\beta(\phi^2)$ instead of $J_\beta(\mu)$. In Lemma 2.2 below it turns out that $J_\beta(\mu) = \infty$ if μ fails to have a Lebesgue density.

In the language of the theory of large deviations, J_β is the rate function that governs a certain large deviation principle. (See Section 4.1 for the notion and some remarks on large deviation theory.) The object that satisfies this principle is the mean of the N normalised occupation measures,

$$\bar{\mu}_{N,\beta} = \frac{1}{N} \sum_{i=1}^N \mu_\beta^{(i)}, \quad N \in \mathbb{N}. \quad (1.6)$$

Here

$$\mu_\beta^{(i)}(dx) = \frac{1}{\beta} \int_0^\beta \delta_{B_s^{(i)}}(dx) ds, \quad i = 1, \dots, N, \quad (1.7)$$

is the *normalised occupation measure* of the i -th motion, which is a random element of $\mathcal{M}_1(\mathbb{R}^d)$. It measures the time spent by the i -th Brownian motion in a given region. One can write the Hamiltonians in terms of the occupation measure as

$$H_{N,\beta} = \beta \sum_{i=1}^N \langle W, \mu_\beta^{(i)} \rangle \quad \text{and} \quad K_{N,\beta} = \beta \sum_{1 \leq i < j \leq N} \langle \mu_\beta^{(i)}, V \mu_\beta^{(j)} \rangle, \quad (1.8)$$

where we denote by V the integral operator with kernel v , i.e., $Vf(x) = \int_{\mathbb{R}^d} v(|x-y|)f(y) dy$ and analogously for measures $V\mu(x) = \int_{\mathbb{R}^d} \mu(dy) v(|x-y|)$. Hence, it is natural to expect that the asymptotic of the Hartree model can be expressed in terms of asymptotic properties of $\bar{\mu}_{N,\beta}$.

We are heading towards a formulation of our main result. Our precise assumptions on the trap potential, W , and on the pair-interaction functional, v , are the following.

Assumption (W). $W: \mathbb{R}^d \rightarrow [0, \infty]$ is continuous in $\{W < \infty\}$ with $\lim_{R \rightarrow \infty} \inf_{|x| > R} W(x) = \infty$. Furthermore, $\{W < \infty\}$ is either equal to \mathbb{R}^d or is a bounded connected open set.

Assumption (v). $v: [0, \infty) \rightarrow [0, \infty]$ is measurable, $\int_{\mathbb{R}^d} v(|x|) dx < \infty$ and $\int_{\mathbb{R}^d} v(|x|)^2 dx < \infty$.

In order to avoid trivialities, we tacitly assume that the support of the initial distribution of the Brownian motions is contained in the set $\{W < \infty\}$.

Now we formulate our main result. As we already indicated, the main role in the analysis of the Hartree model is played by the mean of the normalised occupation measures in (1.6).

Theorem 1.1 (Many-particle limit for the Hartree model). *Assume that $d \in \{2, 3\}$ and let W and v satisfy Assumptions (W) and (v), respectively. Introduce*

$$\alpha(v) := \int_{\mathbb{R}^d} v(|y|) dy < \infty. \quad (1.9)$$

Fix $\beta > 0$. Then, as $N \rightarrow \infty$, the mean $\bar{\mu}_{N,\beta} = \frac{1}{N} \sum_{i=1}^N \mu_\beta^{(i)}$ of the normalised occupation measures satisfies a large deviation principle on $\mathcal{M}_1(\mathbb{R}^d)$ under the measure with density $e^{-H_{N,\beta} - K_{N,\beta}^{(N)}}$ with speed $N\beta$ and rate function

$$I_\beta^{(\otimes)}(\mu) = \begin{cases} J_\beta(\phi^2) + \langle W, \phi^2 \rangle + \frac{1}{2}\alpha(v) \|\phi\|_4^4 & \text{if } \phi^2 = \frac{d\mu}{dx} \text{ exists,} \\ \infty & \text{otherwise.} \end{cases} \quad (1.10)$$

The level sets $\{\mu \in \mathcal{M}_1(\mathbb{R}^d) : I_\beta^{(\otimes)}(\mu) \leq c\}$, $c \in \mathbb{R}$, are compact.

We also write $I_\beta^{(\otimes)}(\phi^2)$ if $\phi^2 = \frac{d\mu}{dx}$. To be more explicit, the large deviation principle for $\bar{\mu}_{N,\beta}$ means that

$$\lim_{N \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} \mathbb{1}_{\bar{\mu}_{N,\beta} \in \cdot} \right] = - \inf_{\phi^2 \in \cdot} I_\beta^{(\otimes)}(\phi^2) \quad \text{weakly,} \quad (1.11)$$

where we identify $\mathcal{M}_1(\mathbb{R}^d)$ with the unit sphere in $L^2(\mathbb{R}^d)$ via the relation $\phi^2(x) dx = \mu(dx)$. The convergence in (1.11) is in the weak sense, i.e., the lower bound holds for open sets and the upper bound for closed sets (see Section 4.1 for more details). Here we refer to the weak topology on $\mathcal{M}_1(\mathbb{R}^d)$. See Section 3.1 for a heuristic explanation of the assertion of Theorem 1.1.

In Assumption (v) we require that $v \circ |\cdot| \in L^2(\mathbb{R}^d)$. This is needed in our proof of the lower bound in (1.11) only. We think that this assumption is technical only and could be relaxed if higher integrability properties of the elements of the level sets of $I_\beta^{(\otimes)}$ were known.

Interesting conclusions of Theorem 1.1 are as follows. For $\alpha > 0$, we introduce the variational formula

$$\chi_\alpha^{(\otimes)}(\beta) = \inf_{\phi \in L^2(\mathbb{R}^d) : \|\phi\|_2=1} \left(J_\beta(\phi^2) + \langle W, \phi^2 \rangle + \frac{1}{2}\alpha \|\phi\|_4^4 \right), \quad (1.12)$$

which, for $\alpha = \alpha(v)$, is the minimum of the rate function $I_\beta^{(\otimes)}$ defined in (1.10). Here are some facts about the minimiser in (1.12).

Lemma 1.2 (Analysis of $\chi_\alpha^{(\otimes)}(\beta)$). *Fix $\beta > 0$ and $\alpha > 0$.*

- (i) *There exists a unique L^2 -normalised minimiser $\phi_* \in L^2(\mathbb{R}^d) \cap L^4(\mathbb{R}^d)$ of the right hand side of (1.12).*
- (ii) *For any neighbourhood $\mathcal{N} \subset L^2(\mathbb{R}^d) \cap L^4(\mathbb{R}^d)$ of ϕ_* ,*

$$\inf_{\phi \in L^2(\mathbb{R}^d) : \|\phi\|_2=1, \phi \notin \mathcal{N}} \left(J_\beta(\phi^2) + \langle W, \phi^2 \rangle + \frac{1}{2}\alpha \|\phi\|_4^4 \right) > \chi_\alpha^{(\otimes)}(\beta).$$

Here ‘neighbourhood’ refers to any of the three following topologies: weakly in L^2 , weakly in L^4 , and weakly in the sense of probability measures, if ϕ is identified with the measure $\phi(x)^2 dx$.

Now we can state some conclusions about the large- N behaviour of the total expectation of the exponential Hamiltonian and about a kind of Law of Large Numbers. The proof is simple and omitted.

Corollary 1.3. *Let the assumptions of Theorem 1.1 be satisfied. Then the following holds.*

(i)

$$\lim_{N \rightarrow \infty} \frac{1}{\beta N} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} \right] = -\chi_{\alpha(v)}^{(\otimes)}(\beta). \quad (1.13)$$

- (ii) As $N \rightarrow \infty$, $\bar{\mu}_{N,\beta}$ converges in distribution under the measure with density $e^{-H_{N,\beta} - K_{N,\beta}^{(N)}}$ towards the measure $\phi_*(x)^2 dx$, where $\phi_* \in L^2(\mathbb{R}^d)$ is the unique minimiser in (1.12) with $\alpha = \alpha(v)$ as defined in (1.9).

1.4 Relation with quantum statistical mechanics.

In this section we explain the relation between the Hartree model in (1.3) and quantum statistical mechanics.

An N -particle quantum system is described by the N -particle Hamilton operator

$$H_N = \sum_{i=1}^N \left[-\Delta_i + W(x_i) \right] + \sum_{1 \leq i < j \leq N} v(|x_i - x_j|), \quad x = (x_1, \dots, x_N) \in \mathbb{R}^{dN}. \quad (1.14)$$

Its spectral analysis, at least for realistic interacting models, is out of reach of contemporary analysis. Rigorous theoretical research started with Bogoliubov and Landau in the 1940ies, followed by Penrose, Feynman and many others. They analysed simplified mathematical models featuring only the most important physical phenomena. However, these approaches turned out to be intuitively appealing and relevant. See [AB04a, AB04b] for a review and some recent results.

Another mathematical approach is to consider systems that are dilute on a particular scale and are kept within a bounded region by the presence of a trap. Here ‘dilute’ means that the range of the interparticle interaction is small compared with the mean particle distance. These systems are supposed to be easier to analyse at least as it concerns the ground state. In a particular dilute situation, the ground states and their energy were analysed in the many-particle limit [LSSY05], see Section 4.2. It turned out that the well-known *Gross-Pitaevskii formula* describes the system remarkably well. This formula, derived independently by Gross and Pitaevskii in 1961 on the basis of the method initiated by Bogoliubov and Landau in the 1940ies, has a parameter $\alpha > 0$ and is defined as follows.

$$\chi_\alpha^{(\text{GP})} = \inf_{\phi \in H^1(\mathbb{R}^d): \|\phi\|_2=1} \left(\|\nabla \phi\|_2^2 + \langle W, \phi^2 \rangle + \frac{1}{2} \alpha \|\phi\|_4^4 \right). \quad (1.15)$$

As was predicted by earlier theoretical work, the only parameter of the pair interaction functional that persists in the limit is its scattering length as a prefactor of the quartic term. See [PS03] for an overview about the physics and [LSSY05] for an account on recent mathematical research.

However, the mathematically rigorous understanding of large quantum systems at *positive* temperature is still incomplete. For dilute systems of *fermions* (i.e., quantum particle systems whose wave functions are antisymmetric under permutation of the single-particle variables), first results for positive temperature are in [Sei06]. One main concern of quantum statistical mechanics is to evaluate the trace of the Boltzmann factor $e^{-\beta H_N}$ for inverse temperature $\beta > 0$ to calculate all thermodynamic functions. The *Feynman-Kac formula* provides a representation of this trace as a functional integral over the space of Brownian paths on the finite time horizon $[0, \beta]$ [Gin71]. This formula is similar to the one in (1.3), where the Brownian motions are conditioned to terminate at their starting points (Brownian bridges) and the initial measure is the Lebesgue measure [Gin71], [BR97]. However, the interaction Hamiltonian is, instead of $K_{N,\beta}$ in (1.2),

$$\sum_{1 \leq i < j \leq N} \int_0^\beta v(|B_s^{(i)} - B_s^{(j)}|) ds. \quad (1.16)$$

This is a *particle* interaction involving only one time axis for all the motions, in contrast to the time-pair integration in (1.2). Note that there is no Hamilton operator such that the total mass of the Hartree model is equal to the trace of the corresponding Boltzmann factor. The Hartree model

features the mutually repellent nature of the trace of $e^{-\beta H_N}$ in a form which is more accessible to a rigorous stochastic analysis.

For describing large systems of *bosons* at positive temperature, one has to consider the trace of the projection of H_N to the subspace of symmetric wave functions. The corresponding Brownian model is given in terms of Brownian bridges with symmetrised initial and terminal conditions. The effect of this symmetrisation on the large- N limit for the non-interacting case is studied in [AK06].

Let us now comment on the physical relevance of the Hartree model in (1.3). We are going to explain that its ground states, i.e., its minimisers of the rate function for the large- β limit [ABK06], correspond to the product ground states of H_N . The product ansatz for the N -particle ground state wave function is known as the Hartree-Bose approximation, see the physics monograph [DN05, Ch. 12].

Recall the integral operator, V , with kernel v , and introduce the variational formula

$$\chi_N^{(\otimes)} = \frac{1}{N} \inf_{h_1, \dots, h_N \in H^1(\mathbb{R}^d): \|h_i\|_2=1 \forall i} \left(\sum_{i=1}^N \left[\|\nabla h_i\|_2^2 + \langle W, h_i^2 \rangle \right] + \sum_{1 \leq i < j \leq N} \langle h_i^2, V h_j^2 \rangle \right). \quad (1.17)$$

Note that there is no convexity argument available, which leads us to the conjecture that the tuples of minimisers are not unique. Note also that

$$\chi_N^{(\otimes)} = \frac{1}{N} \inf_{h_1, \dots, h_N \in H^1(\mathbb{R}^d): \|h_i\|_2=1 \forall i} \langle h, H_N h \rangle, \quad \text{where } h = h_1 \otimes \dots \otimes h_N. \quad (1.18)$$

Hence, one can conceive $\chi_N^{(\otimes)}$ as the *ground product-state energy* of H_N , i.e., as the ground state energy of the restriction of H_N to the set of N -fold product states. If $(h_1^{(N)}, \dots, h_N^{(N)})$ is a minimiser, we call $h^{(N)} := h_1^{(N)} \otimes \dots \otimes h_N^{(N)}$ a *ground product-state*. One of the main results of [ABK06], Th. 1.7, states that, for any fixed $N \in \mathbb{N}$,

$$\lim_{\beta \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} [e^{-H_{N,\beta} - K_{N,\beta}}] = -\chi_N^{(\otimes)}. \quad (1.19)$$

The proof shows that the tuple of normalised occupation measures, $(\mu_\beta^{(1)}, \dots, \mu_\beta^{(N)})$ (recall (1.7)) stands in a one-to-one relation with the minimiser tuples (h_1, \dots, h_N) of (1.17), in the sense of a large deviation principle, analogously to (1.11). This result illustrates the close connection between the zero-temperature Hartree model and the ground state of the Hamilton operator H_N .

It is instructive to compare the main result of the present paper, Theorem 1.1, to the zero-temperature analogue of that result, which we derived in [ABK06] and which served us as a main motivation for the present work. It turned out there that the Gross-Pitaevskii formula well approximates the ground product-state energy $\chi_N^{(\otimes)}$ in the large- N limit, provided that the interaction functional v is rescaled in the same manner as in (1.4). The following is [ABK06, Th. 1.14].

Theorem 1.4 (Large- N asymptotic of $\chi_N^{(\otimes)}$). *Let $d \in \{2, 3\}$. Assume that v satisfies Assumption (v). Replace v by $v_N(\cdot) = N^{d-1}v(N \cdot)$. Let $(h_1^{(N)}, \dots, h_N^{(N)})$ be any minimiser on the right hand side of (1.17) (with v replaced by $v_N(\cdot) = N^{d-1}v(N \cdot)$). Define $\phi_N^2 = \frac{1}{N} \sum_{i=1}^N (h_i^{(N)})^2$. Then we have*

$$\lim_{N \rightarrow \infty} \chi_N^{(\otimes)} = \chi_{\alpha(v)}^{(\text{GP})} \quad \text{and} \quad \phi_N^2 \rightarrow (\phi_{\alpha(v)}^{(\text{GP})})^2,$$

where $\alpha(v)$ is the integral introduced in (1.9). The convergence of ϕ_N^2 is in the weak $L^1(\mathbb{R}^d)$ -sense and weakly for the probability measures $\phi_n^2(x) dx$ towards the measure $(\phi_{\alpha(v)}^{(\text{GP})})^2(x) dx$.

See Section 4.2 for the analogous result for the ground state of H_N . Note that in $d = 2$ the scaling of v differs from the one used in Theorem 1.4. Moreover, the parameter $\alpha(v)$ in Theorem 1.4 is replaced by the scattering length of v in the result of Lieb *et al.* The integral $\alpha(v)$ is known as the *first Born approximation* of the scattering length of v [LSSY05].

We conjecture that $\chi_\alpha^{(\otimes)}(\beta)$ in (1.12) converges to the Gross-Pitaevskii formula as $\beta \rightarrow \infty$. A proof of this is deferred to future work.

2. VARIATIONAL ANALYSIS

In this section we derive some useful properties of the probabilistic energy functional J_β introduced in (1.5) in Section 2.1, and prove the existence and uniqueness of minimisers in the variational formula $\chi_\alpha^{(\otimes)}(\beta)$ introduced in (1.12) in Section 2.2.

2.1 Some properties of J_β .

First we show that J_β is not identically equal to $+\infty$.

Lemma 2.1. *There is $\mu \in \mathcal{M}_1(\mathbb{R}^d)$ such that $J_\beta(\mu) < \infty$.*

Proof. Recall that J_β is the Legendre-Fenchel transform of the map $\mathcal{C}_b(\mathbb{R}^d) \ni f \mapsto \log \mathbb{E}[e^{\beta \langle f, \mu_\beta \rangle}]$, where we recall that μ_β is the normalised occupation measure of one of the Brownian motions. Recall the mean of the N normalised occupation measures from (1.6). Now pick a continuous function $g: \mathbb{R}^d \rightarrow [0, \infty)$ satisfying $\lim_{R \rightarrow \infty} \inf_{|x| \geq R} g(x) = \infty$. Then we have, for any $C > 0$, by splitting the probability space into $\{\langle g, \bar{\mu}_{N,\beta} \rangle \leq C\}$ and its complement,

$$\begin{aligned} -\infty < \log \mathbb{E}[e^{-\langle g, \mu_\beta \rangle}] &= \limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}[e^{-N \langle g, \bar{\mu}_{N,\beta} \rangle}] \\ &\leq \max \left\{ -C, \limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}[e^{-N \langle g, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{\{\langle g, \bar{\mu}_{N,\beta} \rangle \leq C\}}] \right\}. \end{aligned}$$

According to [DZ98, Th. 4.5.3(b)], the sequence $(\bar{\mu}_{N,\beta})_{N \in \mathbb{N}}$ satisfies the upper bound in the large deviation principle for compact sets with rate function equal to J_β . By Prohorov's Theorem, the set $\{\mu \in \mathcal{M}_1(\mathbb{R}^d): \langle g, \mu \rangle \leq C\}$ is compact. Furthermore, note that the map $\mu \mapsto -\langle g, \mu \rangle$ is upper semi continuous. Hence, the upper-bound part in Varadhan's Lemma, [DZ98, Lemma 4.3.6], implies that

$$\limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E}[e^{-N \langle g, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{\{\langle g, \bar{\mu}_{N,\beta} \rangle \leq C\}}] \leq - \inf_{\mu \in \mathcal{M}_1(\mathbb{R}^d): \langle g, \mu \rangle \leq C} \left(\langle g, \mu \rangle + J_\beta(\mu) \right).$$

Picking C large enough, we find that

$$\infty > \inf_{\mu \in \mathcal{M}_1(\mathbb{R}^d): \langle g, \mu \rangle \leq C} \left(\langle g, \mu \rangle + J_\beta(\mu) \right).$$

This implies that J_β is not identically equal to ∞ . \square

Now we show that J_β is infinite in any probability measure in \mathbb{R}^d that fails to have a Lebesgue density.

Lemma 2.2. *If $\mu \in \mathcal{M}_1(\mathbb{R}^d)$ is not absolutely continuous, then $J_\beta(\mu) = \infty$.*

Proof. We write λ for the Lebesgue measure on \mathbb{R}^d . Pick $\mu \in \mathcal{M}_1(\mathbb{R}^d)$ that is not absolutely continuous. Then there is a Borel set $A \subset \mathbb{R}^d$ such that $\lambda(A) = 0$ and $\mu(A) > 0$. Let $M > 0$. We show that $J_\beta(\mu) \geq M$. Pick $K = \frac{4M}{\mu(A)}$ and $\eta = \frac{1}{2}\mu(A)$. We may assume that $2 \leq e^{\beta \frac{K}{4} \mu(A)}$. Let $(Q_\varepsilon)_{\varepsilon > 0}$ be an increasing family of open subsets of \mathbb{R}^d such that $A \subset Q_\varepsilon$ and $\lambda(Q_\varepsilon) < \varepsilon$ for any $\varepsilon > 0$. Let μ_β be the (random) normalised occupation measure of a Brownian motion $(B_s)_{s \geq 0}$. Pick $\varepsilon > 0$ and $\delta > 0$ so small that

$$\mathbb{P}\left(\mu_\beta(U_\delta(Q_\varepsilon)) > \eta\right) < e^{-\beta K(1-\eta)},$$

where $U_\delta(Q_\varepsilon)$ is the δ -neighbourhood of Q_ε . This is possible since

$$\limsup_{\varepsilon \downarrow 0} \limsup_{\delta \downarrow 0} \mu_\beta(U_\delta(Q_\varepsilon)) = \limsup_{\varepsilon \downarrow 0} \mu_\beta(\overline{Q_\varepsilon}) = \mu_\beta\left(\bigcap_{\varepsilon > 0} \overline{Q_\varepsilon}\right) = 0 \quad \text{a.s.}$$

Now we pick a function $f \in \mathcal{C}_b(\mathbb{R}^d)$ such that $0 \leq f \leq K$, $\text{supp}(f) \subset U_\delta(Q_\varepsilon)$ and $f|_{Q_\varepsilon} = K$. Then $\langle f, \mu \rangle \geq \int_{Q_\varepsilon} f(x) \mu(dx) \geq K\mu(A)$. Furthermore,

$$\begin{aligned} \mathbb{E}\left[e^{\int_0^\beta f(B_s) ds}\right] &= \mathbb{E}\left[e^{\beta\langle f, \mu_\beta \rangle} \mathbb{1}_{\{\mu_\beta(U_\delta(Q_\varepsilon)) \leq \eta\}}\right] + \mathbb{E}\left[e^{\beta\langle f, \mu_\beta \rangle} \mathbb{1}_{\{\mu_\beta(U_\delta(Q_\varepsilon)) > \eta\}}\right] \\ &\leq e^{\beta\eta K} + e^{\beta K} \mathbb{P}(\mu_\beta(U_\delta(Q_\varepsilon)) > \eta) \\ &\leq e^{\beta\eta K} + e^{\beta K} e^{-\beta K(1-\eta)} \leq 2e^{\beta\eta K} \leq e^{\beta K \frac{3}{4}\mu(A)}. \end{aligned} \quad (2.1)$$

Hence,

$$J_\beta(\mu) \geq \langle f, \mu \rangle - \frac{1}{\beta} \log \mathbb{E}\left[e^{\int_0^\beta f(B_s) ds}\right] \geq K\mu(A) - K\frac{3}{4}\mu(A) = M.$$

□

In general, the supremum in the definition (1.5) of J_β is not attained. It is of interest to replace the function class $\mathcal{C}_b(\mathbb{R}^d)$ in (1.5) by some class of better behaved functions. In particular, one would like to use only functions f that are extremely negative far out. This is of course possible only if ϕ^2 decays sufficiently fast at infinity. We write μ_β for the normalised occupation measure of the Brownian motion $(B_s^{(1)})_{s \geq 0}$ in the following. By \mathfrak{m} we denote the initial distribution of the Brownian motions.

Lemma 2.3 (Alternate expression for J_β). *Let $W: \mathbb{R}^d \rightarrow [0, \infty]$ be continuous in $\{W < \infty\}$, which is supposed to contain $\text{supp}(\mathfrak{m})$ and to be either equal to \mathbb{R}^d or compact. Fix $\phi \in L^2(\mathbb{R}^d)$ satisfying $\langle W, \phi^2 \rangle < \infty$. Then*

$$J_\beta(\phi^2) = \sup_{h \in \mathcal{C}_b(\mathbb{R}^d)} \left(\langle -W + h, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E}\left[e^{\beta\langle -W + h, \mu_\beta \rangle}\right] \right). \quad (2.2)$$

Proof. Let $J_{W,\beta}(\phi^2)$ denote the right-hand side of (2.2). We first prove ‘ \geq ’ in (2.2). Let $h \in \mathcal{C}_b(\mathbb{R}^d)$. We may assume that $h \leq 0$ (otherwise we add a suitable constant to h). Then $f_R = (-W + h) \vee (-R)$ is a bounded continuous function for any $R > 0$ with $\langle -W + h, \phi^2 \rangle \leq \langle f_R, \phi^2 \rangle$. Furthermore, $f_R \downarrow -W + h$ as $R \rightarrow \infty$, hence the monotonous convergence theorem yields that

$$\lim_{R \rightarrow \infty} \mathbb{E}\left[e^{\beta\langle f_R, \mu_\beta \rangle}\right] = \mathbb{E}\left[e^{\beta\langle -W + h, \mu_\beta \rangle}\right].$$

This shows that $J_\beta(\phi^2) \geq J_{W,\beta}(\phi^2)$ holds. Note that we did not need here that $\langle W, \phi^2 \rangle < \infty$.

Now we prove ‘ \leq ’ in (2.2). Let $f \in \mathcal{C}_b(\mathbb{R}^d)$ be given. For $R > 0$, consider $h_R = (f + W) \wedge R$, then $h_R \in \mathcal{C}_b(\mathbb{R}^d)$ with $h_R \uparrow f + W$. Since $\langle W, \phi^2 \rangle < \infty$, we have

$$\liminf_{R \rightarrow \infty} \langle -W + h_R, \phi^2 \rangle \geq \langle f, \phi^2 \rangle.$$

Furthermore, by the monotonous convergence theorem,

$$\lim_{R \rightarrow \infty} \mathbb{E}\left[e^{\beta\langle -W + h_R, \mu_\beta \rangle}\right] = \mathbb{E}\left[e^{\beta\langle f, \mu_\beta \rangle}\right].$$

This implies that ‘ \leq ’ holds in (2.2). □

Let us draw a conclusion for compactly supported functions ϕ . For a measurable set $A \subset \mathbb{R}^d$, we denote by $\mathcal{C}_b(A)$ the set of continuous bounded functions $A \rightarrow \mathbb{R}$.

Corollary 2.4. *Fix $\phi \in L^2(\mathbb{R}^d)$ satisfying $\|\phi\|_2 = 1$. If the support of ϕ is compact, connected and contains $\text{supp}(\mathfrak{m})$, then*

$$J_\beta(\phi^2) = \sup_{f \in \mathcal{C}_b(\text{supp}(\phi))} \left(\langle f, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E}\left[e^{\beta\langle f, \mu_\beta \rangle} \mathbb{1}_{\{\text{supp}(\mu_\beta) \subset \text{supp}(\phi)\}}\right] \right). \quad (2.3)$$

Proof. We pick $W = \infty \mathbb{1}_{\text{supp}(\phi)}$ in Lemma 2.3 and see that, on the right hand side of (2.2), we may insert the indicator on $\{\text{supp}(\mu_\beta) \subset \text{supp}(\phi)\}$ in the expectation and can drop W in the exponent. Hence, both this expectation and the first term, $\langle -W + f, \phi^2 \rangle$, do not depend on the values of f outside $\text{supp}(\phi)$. \square

The next lemma shows the interplay between the arguments for the functional J_β and the fixed initial distribution of the Brownian motions.

Lemma 2.5. *Let $\phi \in L^2(\mathbb{R}^d)$ satisfying $\|\phi\|_2 = 1$. If $\text{dist}(\text{supp}(\phi), \text{supp}(\mathbf{m})) > 0$, then $J_\beta(\phi^2) = +\infty$.*

Proof. Let S be an open neighbourhood of $\text{supp}(\phi)$ with $\delta = \text{dist}(S, \text{supp}(\mathbf{m})) > 0$. Pick $K > 0$ and a continuous bounded function $f: \mathbb{R}^d \rightarrow [0, K]$ with $\text{supp}(f) \subset S$ and $f|_{\text{supp}(\phi)} = K$. Then $\langle f, \phi^2 \rangle = K$. Then we have

$$\begin{aligned} \mathbb{E}[e^{\beta \langle f, \mu_\beta \rangle}] &= \mathbb{E}[e^{\beta \langle f, \mu_\beta \rangle} \mathbb{1}\{\mu_\beta(S) < 1 - K^{-1/2}\}] + \mathbb{E}[e^{\beta \langle f, \mu_\beta \rangle} \mathbb{1}\{\mu_\beta(S) > 1 - K^{-1/2}\}] \\ &\leq e^{\beta K(1 - K^{-1/2})} + e^{\beta K} \mathbb{P}\left(\sup_{0 \leq t \leq K^{-1/2}} |B_t| \geq \delta\right) \\ &\leq e^{\beta K} \left(e^{-\beta K^{1/2}} + \frac{2}{\sqrt{2\pi}} e^{-\frac{1}{2}\delta^2 K^{1/2}} \right). \end{aligned} \tag{2.4}$$

Hence,

$$J_\beta(\phi^2) \geq \langle f, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E}[e^{\beta \langle f, \mu_\beta \rangle}] \geq -\frac{1}{\beta} \log \left(e^{-\beta K^{1/2}} + \frac{2}{\sqrt{2\pi}} e^{-\frac{1}{2}\delta^2 K^{1/2}} \right).$$

Letting $K \rightarrow \infty$ shows that $J_\beta(\phi^2) = +\infty$. \square

2.2 Analysis of $\chi_\alpha^{(\otimes)}(\beta)$.

Proof of Lemma 1.2. The uniqueness of the minimiser follows from the convexity of the functionals J_β and $\langle W, \cdot \rangle$, together with the strict convexity of $\phi^2 \mapsto \|\phi\|_4^4$.

Let $(\phi_n)_{n \in \mathbb{N}}$ be an approximative sequence of minimisers for the formula in (1.12), i.e., $\phi_n \in L^2(\mathbb{R}^d)$, $\|\phi_n\|_2 = 1$ for any $n \in \mathbb{N}$ and

$$\lim_{n \rightarrow \infty} \left(J_\beta(\phi_n^2) + \langle W, \phi_n^2 \rangle + \frac{1}{2} \alpha \|\phi_n\|_4^4 \right) = \chi_\alpha^{(\otimes)}(\beta).$$

In particular, the sequences $(J_\beta(\phi_n^2))_n$, $(\langle W, \phi_n^2 \rangle)_n$ and $(\|\phi_n\|_4^4)_n$ are bounded. Since W explodes at infinity by Assumption (W), the sequence of probability measures $(\phi_n^2(x) dx)_{n \in \mathbb{N}}$ is tight. According to Prohorov's Theorem, there is a probability measure μ on \mathbb{R}^d such that $\phi_n^2(x) dx$ converges weakly towards μ as $n \rightarrow \infty$, along a suitable subsequence. Since the sequence $(\phi_n^2)_n$ is bounded in $L^2(\mathbb{R}^d)$, the Banach-Alaoglu Theorem implies that we may assume that, along the same sequence, $(\phi_n^2)_n$ converges weakly in $L^2(\mathbb{R}^d)$ towards some $\phi^2 \in L^2(\mathbb{R}^d)$. Since J_β is weakly lower semi continuous (in the sense of probability measures), we get

$$\liminf_{n \rightarrow \infty} J_\beta(\phi_n^2) \geq J_\beta(\mu),$$

and with Lemma 2.2 we conclude that $\mu(dx) = \tilde{\phi}^2(x) dx$ for some function $\tilde{\phi}^2 \in L^2(\mathbb{R}^d)$ with $\|\tilde{\phi}\|_2 = 1$. By the weak convergence in $L^2(\mathbb{R}^d)$, combined with the weak convergence in the sense of probability measures, for any continuous bounded function ψ with compact support we have $\langle \psi, \phi^2 \rangle = \langle \psi, \tilde{\phi}^2 \rangle$. Hence, we get $\phi^2 = \tilde{\phi}^2$ a.e.. As J_β is weakly lower semi continuous (in the sense of probability measures), $\|\cdot\|_4$ is L^4 -weakly lower semi continuous, and $\phi \mapsto \langle W, \phi^2 \rangle$ is lower semi continuous, we have that

$$\begin{aligned} J_\beta(\phi^2) + \langle W, \phi^2 \rangle + \frac{1}{2} \alpha(v) \|\phi\|_4^4 &\leq \liminf_{n \rightarrow \infty} \left(J_\beta(\phi_n^2) + \langle W, \phi_n^2 \rangle + \frac{1}{2} \alpha(v) \|\phi_n\|_4^4 \right) \\ &= \chi_\alpha^{(\otimes)}(\beta). \end{aligned}$$

This shows that the limiting point ϕ is the minimiser in (1.12). This ends the proof of Lemma 1.2(i). Furthermore, the proof also shows that the minimising sequence converges, along some subsequence, towards the unique minimiser in all the three weak senses: in L^2 , L^4 and weakly as a probability measures. This implies Lemma 1.2(ii). \square

3. LARGE- N BEHAVIOUR: PROOF OF THEOREM 1.1

In this section we prove Theorem 1.1. We shall proceed according to the well-known Gärtner-Ellis theorem, which relates logarithmic asymptotic of probabilities to the ones of expectations of exponential integrals. Therefore, we have to establish the existence of the logarithmic moment generating function of $\bar{\mu}_{N,\beta}$ under the measure with density $e^{-H_{N,\beta} - K_{N,\beta}^{(N)}}$. The main step in the proof of Theorem 1.1 is the following.

Proposition 3.1 (Asymptotic for the cumulant generating function). *For any $f \in \mathcal{C}_b(\mathbb{R}^d)$ the cumulant generating function exists, i.e.,*

$$\lim_{N \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] = -\chi^{(\otimes)}(f), \quad (3.1)$$

where

$$\chi^{(\otimes)}(f) = \frac{1}{\beta} \inf_{\phi \in L^2(\mathbb{R}^d): \|\phi\|_2^2=1} \left\{ J_\beta(\phi^2) + \langle W - f, \phi^2 \rangle + \frac{1}{2} \alpha(v) \|\phi\|_4^4 \right\}. \quad (3.2)$$

Indeed, Theorem 1.1 follows from Proposition 3.1 as follows.

Proof of Theorem 1.1. We are going to use the Gärtner-Ellis Theorem, see [DZ98, Cor. 4.6.14]. For this, we only have to show that the sequence of the $\bar{\mu}_{N,\beta}$ is exponentially tight under measure with density $e^{-H_{N,\beta} - K_{N,\beta}^{(N)}}$ and that the map $f \mapsto \chi^{(\otimes)}(f)$ is Gâteaux differentiable.

The proof of exponential tightness is easily done using our assumption that $\lim_{R \rightarrow \infty} \inf_{|x| \geq R} W(x) = \infty$ in combination with the theorems by Prohorov and Portmanteau; we omit the details.

Fix $f \in \mathcal{C}_b(\mathbb{R}^d)$. The proof of Lemma 1.2 shows that the infimum in the formula of the right hand side of (3.2) is attained. Let $\phi_f^2 \in L^1(\mathbb{R}^d)$ be the minimiser for the right hand side of (3.2), and, for some $g \in \mathcal{C}_b(\mathbb{R}^d)$, let $\phi_{f+tg}^2 \in L^1(\mathbb{R}^d)$, $t > 0$, be corresponding minimiser for $f + tg$ instead of f . We obtain

$$\frac{1}{t} \left[\chi^{(\otimes)}(f + tg) - \chi^{(\otimes)}(f) \right] \geq -\frac{1}{\beta} \langle g, \phi_{f+tg}^2 \rangle. \quad (3.3)$$

Similarly to the proof of Lemma 1.2, one sees that ϕ_{f+tg}^2 converges, as $t \downarrow 0$, weakly (in the sense of probability measures) towards the minimiser ϕ_f^2 of the right hand side of (3.2). Therefore, it is clear that the right hand side of (3.3) converges towards $\langle g, \phi_f^2 \rangle$. Analogously, one shows the complementary bound. This implies the Gâteaux-differentiability of $\chi^{(\otimes)}$ with

$$\frac{\partial}{\partial g} \chi^{(\otimes)}(f) = \langle g, \phi_f^2 \rangle.$$

\square

In Section 3.1 we give a heuristic explanation of (3.1) and introduce the Brownian intersection local times, an important object in our proof. In Sections 3.2 and 3.3, respectively, we prove the upper and the lower bound in (3.1).

3.1 Heuristics and Brownian intersection local times

In this section, we give a heuristic explanation of the assertion of Proposition 3.1. We rewrite the two Hamiltonians in terms of functionals of the mean $\bar{\mu}_{N,\beta}$ defined in (1.6) and use a well-known large deviation principle for $\bar{\mu}_{N,\beta}$. In particular, we introduce an object that will play an important role in the proofs, the Brownian intersection local times. For the definition and the most important facts on large deviation theory used, see the Appendix or consult [DZ98].

Rewriting the first Hamiltonian in terms of $\bar{\mu}_{N,\beta}$ is an easy task and can be done for any fixed N :

$$H_{N,\beta} = N\beta \int_{\mathbb{R}^d} W(x) \frac{1}{N} \sum_{i=1}^N \mu_\beta^{(i)}(dx) = N\beta \langle W, \bar{\mu}_{N,\beta} \rangle. \quad (3.4)$$

Now we rewrite the second Hamiltonian, which will need Brownian intersection local times and an approximation for large N . Let us first introduce the intersection local times, see [GHR84]. For the following, we have to restrict to the case $d \in \{2, 3\}$.

Fix $1 \leq i < j \leq N$ and consider the process $B^{(i)} - B^{(j)}$, the so-called *confluent Brownian motion* of $B^{(i)}$ and $-B^{(j)}$. This two-parameter process possesses a local time process, i.e., there is a random process $(L_\beta^{(i,j)}(x))_{x \in \mathbb{R}^d}$ such that, for any bounded and measurable function $f: \mathbb{R}^d \rightarrow \mathbb{R}$,

$$\int_{\mathbb{R}^d} f(x) L_\beta^{(i,j)}(x) dx = \frac{1}{\beta^2} \int_0^\beta ds \int_0^\beta dt f(B_s^{(i)} - B_t^{(j)}) = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \mu_\beta^{(i,j)}(dx) \mu_\beta^{(i,j)}(dy) f(x - y). \quad (3.5)$$

Hence, we may rewrite $K_{N,\beta}^{(N)}$ as follows:

$$\begin{aligned} K_{N,\beta}^{(N)} &= \beta N^{d-1} \sum_{1 \leq i < j \leq N} \int_{\mathbb{R}^d} v(zN) L_\beta^{(i,j)}(z) dz \\ &= N\beta \int_{\mathbb{R}^d} v(x) \frac{1}{N^2} \sum_{1 \leq i < j \leq N} L_\beta^{(i,j)}\left(\frac{1}{N}x\right) dx. \end{aligned} \quad (3.6)$$

It is known [GHR84, Th. 1] that $(L_\beta^{(i,j)}(x))_{x \in \mathbb{R}^d}$ may be chosen continuously in the space variable. Furthermore, the random variable $L_\beta^{(i,j)}(0) = \lim_{x \rightarrow 0} L_\beta^{(i,j)}(x)$ is equal to the normalised total intersection local time of the two motions $B^{(i)}$ and $B^{(j)}$ up to time β . Formally,

$$L_\beta^{(i,j)}(0) = \frac{1}{\beta^2} \int_A dx \int_0^\beta ds \frac{\mathbb{1}\{B_s^{(i)} \in dx\}}{dx} \int_0^\beta dt \frac{\mathbb{1}\{B_t^{(j)} \in dx\}}{dx} = \int_A dx \frac{\mu_\beta^{(i)}(dx)}{dx} \frac{\mu_\beta^{(j)}(dx)}{dx}, \quad (3.7)$$

Using the continuity of $L_\beta^{(i,j)}$, we approximate

$$\begin{aligned} K_{N,\beta}^{(N)} &\approx N\beta \frac{1}{2} \alpha(v) \frac{2}{N^2} \sum_{1 \leq i < j \leq N} L_\beta^{(i,j)}(0) \approx N\beta \frac{1}{2} \alpha(v) \left\langle \frac{1}{N} \sum_{i=1}^N \mu_\beta^{(i)}, \frac{1}{N} \sum_{i=1}^N \mu_\beta^{(i)} \right\rangle \\ &= N\beta \frac{1}{2} \alpha(v) \left\| \frac{d\bar{\mu}_{N,\beta}}{dx} \right\|_2^2. \end{aligned}$$

where we conceive $\mu_\beta^{(i)}$ as densities, like in (3.7).

The main ingredient is now that $(\bar{\mu}_{N,\beta})_{N \in \mathbb{N}}$ satisfies a large deviation principle on $\mathcal{M}_1(\mathbb{R}^d)$ with speed $N\beta$ and rate function J_β . This fact directly follows from Cramér's Theorem, together with the exponential tightness of the sequence $(\bar{\mu}_{N,\beta})_{N \in \mathbb{N}}$. Hence, using Varadhan's Lemma and ignoring the missing continuity of the map $\mu \mapsto \left\| \frac{d\mu}{dx} \right\|_2^2$, this heuristic explanation is finished by

$$\begin{aligned} \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] &\approx \mathbb{E} \left[\exp \left\{ -N\beta \left[\langle W - f, \bar{\mu}_{N,\beta} \rangle - \frac{1}{2} \alpha(v) \left\| \frac{d\bar{\mu}_{N,\beta}}{dx} \right\|_2^2 \right] \right\} \right] \\ &\approx e^{-N\beta \chi^{(\otimes)}(f)}, \end{aligned}$$

Here we substituted $\phi^2(x) dx = \mu(dx)$ and noticed that, according to Lemma 2.2, we may restrict the infimum over probability measures to the set of their Lebesgue densities ϕ^2 .

3.2 Proof of the upper bound in (3.1) in Proposition 3.1

In this section we prove the upper bound in 3.1 in Proposition 3.1. Our proof goes along the lines of the argument sketched in Section 3.1. However, in order to arrive at a setting in which we may apply Cramér's Theorem and Varadhan's Lemma, we will have to prepare with a number of technical steps. More precisely, we will have to estimate the interaction term $K_{N,\beta}^{(N)}$ from below in terms of a smoothed version of the intersection local times. This version will turn out to be a bounded and continuous functional of the mean of the normalised occupation times measures, $\bar{\mu}_{N,\beta}$, which are the central object of the analysis.

Our strategy is as follows. First, we distinguish those events on which, for at least $((1-\eta)N)^2$ pairs (i, j) of indices, the intersection local times $L^{(i,j)}(x)$ for $|x| \leq 2\varepsilon$ are sufficiently close to $L^{(i,j)}(0)$, and its complement. More precisely, we will have $|L^{(i,j)}(x) - L^{(i,j)}(0)| < \xi$ for these (i, j) and x . Here ξ, η, ε are positive parameters which will eventually be sent to zero. (The complement of the event considered will turn out to be small by the continuity of the intersection local times in zero.) The replacement of $L^{(i,j)}(x)$ by $L^{(i,j)}(0)$ will require a space cutting argument, i.e., we will restrict the interaction from \mathbb{R}^d to the cube $Q_R = [-R, R]^d$ for some $R > 0$ which will eventually be sent to infinity. Our second main step is to replace $L^{(i,j)}(0)$ by the smoothed version $L^{(i,j)} * \kappa_\varepsilon * \kappa_\varepsilon(0)$, where κ_ε is a smooth approximation of the Dirac function δ_0 as $\varepsilon \downarrow 0$. The smoothed intersection local times can easily be written as a continuous bounded functional of the mean of the normalised occupation times measures, $\bar{\mu}_{N,\beta}$. Hence, Cramér's Theorem and Varadhan's Lemma become applicable, and we arrive at an upper bound for the large- N rate in terms of an explicit variational formula, which depends on the parameters. Finally, we send the parameters to zero and infinity, respectively.

Let us come to the details. Introduce the following random set of index pairs,

$$D_N = D_N(\varepsilon, \xi) = \left\{ (i, j) \in \{1, \dots, N\}^2 \setminus \Delta_N : \sup_{|x| \leq 2\varepsilon} |L_\beta^{(i,j)}(0) - L_\beta^{(i,j)}(x)| < \xi \right\}, \quad (3.8)$$

where $\Delta_N = \{(i, i) : i \in \{1, \dots, N\}\}$ denotes the diagonal in $\{1, \dots, N\}^2$. Fix $\eta > 0$ and consider the event

$$A_N = A_N(\varepsilon, \xi, \eta) = \left\{ \exists I \subset \{1, \dots, N\} : I \times I \setminus \Delta_N \subset D_N, |I| \geq (1-\eta)N \right\} \quad (3.9)$$

In words, on A_N , there is a quite large set I of indices such that all pairs (i, j) of distinct indices in I satisfy $|L_\beta^{(i,j)}(0) - L_\beta^{(i,j)}(x)| < \xi$ for all $|x| \leq 2\varepsilon$.

First we show that the contribution coming from the complement A_N^c vanishes for small ε :

Lemma 3.2 (A_N^c is negligible). *For any $\xi > 0$ and any $\eta \in (0, \frac{1}{2})$,*

$$\lim_{\varepsilon \rightarrow 0} \limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{A_N^c(\varepsilon, \xi, \eta)} \right] = -\infty. \quad (3.10)$$

Proof. Since $H_{N,\beta}$, $K_{N,\beta}^{(N)}$ and f are bounded from below, it suffices to show that

$$\lim_{\varepsilon \rightarrow 0} \limsup_{N \rightarrow \infty} \frac{1}{N} \log \mathbb{P}(A_N^c(\varepsilon, \xi, \eta)) = -\infty. \quad (3.11)$$

Note that

$$A_N^c = A_N^c(\varepsilon, \xi, \eta) = \{ \forall I \subset \{1, \dots, N\} : |I| \geq (1-\eta)N \implies (I \times I) \setminus \Delta_N \not\subset D_N \}. \quad (3.12)$$

First we show that, on A_N^c , there are pairwise different integers $i_1, j_1, i_2, j_2, \dots, i_{\lfloor \eta N/3 \rfloor}, j_{\lfloor \eta N/3 \rfloor}$ in $\{1, \dots, N\}$ such that $(i_l, j_l) \in D_N^c$ for all $l = 1, \dots, \lfloor \eta N/3 \rfloor$.

We construct the indices inductively. Consider $I_1 = \{1, \dots, \lceil(1 - \eta)N\rceil\}$, then

$$I_1 \times I_1 \setminus \Delta_N \not\subset D_N,$$

i.e., there is a pair $(i_1, j_1) \in (I_1 \times I_1 \setminus \Delta_N) \cap D_N^c$. Also the set

$$I_2 = (I_1 \setminus \{i_1, j_1\}) \cup \{(1 - \eta)N + 1, (1 - \eta)N + 2\}$$

has no less than $(1 - \eta)N$ elements. Hence there is a pair $(i_2, j_2) \in (I_2 \times I_2 \setminus \Delta_N) \cap D_N^c$. Clearly $\sharp\{i_1, j_1, i_2, j_2\} = 4$. In this way, we can proceed altogether at least $\lfloor \frac{1}{2}\eta N \rfloor$ times. This procedure constructs the indices $i_1, j_1, i_2, j_2, \dots, i_{\lfloor \eta N/3 \rfloor}, j_{\lfloor \eta N/3 \rfloor}$ pairwise different such that $(i_1, j_1), \dots, (i_{\lfloor \eta N/3 \rfloor}, j_{\lfloor \eta N/3 \rfloor}) \in D_N^c$.

Now we prove that (3.11) holds. We abbreviate ‘p.d.’ for ‘pairwise disjoint’ in the following. For notational convenience, we drop the brackets $\lfloor \cdot \rfloor$. Because of the preceding, we have

$$\begin{aligned} \mathbb{P}(A_N^c(\varepsilon, \xi, \eta)) &\leq \sum_{i_1, j_1, \dots, i_{\eta N/3}, j_{\eta N/3} \in \{1, \dots, N\}, \text{p.d.}} \mathbb{P}\left(\forall l = 1, \dots, \eta N/3: \sup_{|x| \leq 2\varepsilon} |L_\beta^{(i_l, j_l)}(x) - L_\beta^{(i_l, j_l)}(0)| \geq \xi\right) \\ &= \binom{N}{2\eta N/3} \mathbb{P}\left(\sup_{|x| \leq 2\varepsilon} |L_\beta^{(1,2)}(x) - L_\beta^{(1,2)}(0)| \geq \xi\right)^{\eta N/3} \\ &\leq \exp\left(-N \left[\log \frac{1}{2} - \frac{\eta}{3} \log \mathbb{P}\left(\sup_{|x| \leq 2\varepsilon} |L_\beta^{(1,2)}(x) - L_\beta^{(1,2)}(0)| \geq \xi\right)\right]\right). \end{aligned} \tag{3.13}$$

Since the process $(L_\beta^{(1,2)}(x))_{x \in \mathbb{R}^d}$ may be chosen continuously in the space variable [GHR84, Th. 1], we have

$$\lim_{\varepsilon \rightarrow 0} \mathbb{P}\left(\sup_{|x| \leq 2\varepsilon} |L_\beta^{(1,2)}(x) - L_\beta^{(1,2)}(0)| \geq \xi\right) = 0. \tag{3.14}$$

This, together with (3.13), concludes the proof. \square

Now we estimate $K_{N,\beta}^{(N)}$ on the event A_N . For $R > 0$, we recall that $Q_R = [-R, R]^d$ and introduce

$$\alpha_R(v) = \int_{Q_R} v(|x|) dx. \tag{3.15}$$

Let $\kappa: \mathbb{R}^d \rightarrow [0, \infty)$ be a smooth function with support in $[-1, 1]^d$ and $\int \kappa(x) dx = 1$. For $\varepsilon > 0$, we define $\kappa_\varepsilon(x) = \varepsilon^{-d} \kappa(x/\varepsilon)$. Then κ_ε is an approximation of δ_0 as $\varepsilon \downarrow 0$, and we have $\text{supp } \kappa_\varepsilon \subset Q_\varepsilon$ and $\int_{\mathbb{R}^d} \kappa_\varepsilon(x) dx = 1$ for any $\varepsilon > 0$.

Lemma 3.3 (Estimating $K_{N,\beta}^{(N)}$ on $A_N(\varepsilon, \xi, \eta)$). *Fix $\varepsilon, \xi, \eta > 0$. Then, for any $R > 0$ and any $N \in \mathbb{N}$ satisfying $N > R/(2\varepsilon)$, on the event $A_N(\varepsilon, \xi, \eta)$,*

$$-K_{N,\beta}^{(N)} \leq -\frac{1}{2} \alpha_R(v) \beta |I| (1 - \eta) \|\bar{\mu}_{I,\beta} * \kappa_\varepsilon\|_2^2 + 2\xi \alpha_R(v) + \frac{\alpha_R(v) \|\kappa_\varepsilon\|_\infty}{N}, \tag{3.16}$$

where the random subset I of $\{1, \dots, N\}$ in (3.9) is chosen minimally with $|I| \geq (1 - \eta)N$ and $(I \times I \setminus \Delta_N) \subset D_N$, and

$$\bar{\mu}_{I,\beta} = \frac{1}{|I|} \sum_{i \in I} \mu_\beta^{(i)} \tag{3.17}$$

denotes the mean of the corresponding normalised occupation measures.

Proof. First, we write the interaction terms for the scaled pair potential v_N as integrals against the intersection local times of two Brownian motions at spatial points x/N . As the pair interaction v is positive we get easily an upper bound, when we restrict the integrations to the box Q_R . On this compact set we use the continuity to get rid of the dependence of the spatial variables in the integrals. We restrict the summation over all pairs of indices to the random set $D_N = D_N(\varepsilon, \xi)$.

Recall (3.6). On the event $A_N(\varepsilon, \xi, \eta)$, we may estimate, for all $N > R/(2\varepsilon)$,

$$\begin{aligned}
-\frac{1}{N\beta}K_{N,\beta}^{(N)} &= -\frac{1}{N^2} \sum_{1 \leq i < j \leq N} \int_{\mathbb{R}^d} v(|x|) L_\beta^{(i,j)}\left(\frac{x}{N}\right) dx \leq -\frac{1}{N^2} \sum_{(i,j) \in D_N} \int_{Q_R} v(|x|) L_\beta^{(i,j)}\left(\frac{x}{N}\right) dx \\
&\leq -\frac{1}{2} \frac{\alpha_R(v)}{N^2} \sum_{(i,j) \in D_N} L_\beta^{(i,j)}(0) + \frac{1}{N^2} \sum_{(i,j) \in D_N} \int_{Q_R} v(|x|) \left| L_\beta^{(i,j)}(0) - L_\beta^{(i,j)}(x/N) \right| dx \\
&\leq -\frac{1}{2} \frac{\alpha_R(v)}{N^2} \sum_{(i,j) \in D_N} L_\beta^{(i,j)}(0) + \frac{\xi |D_N|}{N^2} \alpha_R(v) \\
&\leq -\frac{1}{2} \frac{\alpha_R(v)}{N^2} \sum_{(i,j) \in D_N} L_\beta^{(i,j)}(0) + \xi \alpha_R(v).
\end{aligned} \tag{3.18}$$

For any $(i, j) \in D_N$, we now replace the intersection local time at zero, $L_\beta^{(i,j)}(0)$, with the smoothed version $L_\beta^{(i,j)} * \kappa_\varepsilon * \kappa_\varepsilon(0)$. The replacement error is estimated by

$$\left| L_\beta^{(i,j)}(0) - L_\beta^{(i,j)} * \kappa_\varepsilon * \kappa_\varepsilon(0) \right| \leq \int_{Q_{2\varepsilon}} dx \kappa_\varepsilon * \kappa_\varepsilon(x) \left| L_\beta^{(i,j)}(0) - L_\beta^{(i,j)}(x) \right| \leq \xi, \quad (i, j) \in D_N. \tag{3.19}$$

Hence, we may continue the estimation in (3.18) by

$$-\frac{1}{N\beta}K_{N,\beta}^{(N)} \leq -\frac{1}{2} \frac{\alpha_R(v)}{N^2} \sum_{(i,j) \in D_N} L_\beta^{(i,j)} * \kappa_\varepsilon * \kappa_\varepsilon(0) + 2\xi \alpha_R(v). \tag{3.20}$$

Recall the defining property on the intersection local time in (3.5). Hence, we can write the smoothed version in terms of a convolution of the normalised occupation measures as follows:

$$\begin{aligned}
L_\beta^{(i,j)} * \kappa_\varepsilon * \kappa_\varepsilon(0) &= \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \mu_\beta^{(i)}(dx) \mu_\beta^{(j)}(dy) dz \kappa_\varepsilon(y-x-z) \kappa_\varepsilon(z) \\
&= \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \mu_\beta^{(i)}(dx) \mu_\beta^{(j)}(dy) dw \kappa_\varepsilon(w-y) \kappa_\varepsilon(w-x) \\
&= \langle \mu_\beta^{(i)} * \kappa_\varepsilon, \mu_\beta^{(j)} * \kappa_\varepsilon \rangle.
\end{aligned} \tag{3.21}$$

To proceed with our estimates from (3.20), we add now the self-intersection terms, i.e., the diagonal terms where $i = j$. The additional terms are bounded by the L^∞ -norm of κ_ε as seen from

$$\begin{aligned}
\langle \mu_\beta^{(i)} * \kappa_\varepsilon, \mu_\beta^{(j)} * \kappa_\varepsilon \rangle &= \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} dx \mu_\beta^{(i)}(dy) \mu_\beta^{(j)}(dz) \kappa_\varepsilon(x-y) \kappa_\varepsilon(x-z) \\
&\leq \|\kappa_\varepsilon\|_\infty \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} dx \mu_\beta^{(i)}(dy) \kappa_\varepsilon(x-y) = \|\kappa_\varepsilon\|_\infty.
\end{aligned} \tag{3.22}$$

Hence, we obtain from (3.20) that

$$-\frac{1}{N\beta}K_{N,\beta}^{(N)} \leq -\frac{1}{2} \frac{\alpha_R(v)}{N^2} \sum_{(i,j) \in D_N \cup \Delta_N} \langle \mu_\beta^{(i)} * \kappa_\varepsilon, \mu_\beta^{(j)} * \kappa_\varepsilon \rangle + 2\xi \alpha_R(v) + \frac{1}{2} \frac{\alpha_R(v) \|\kappa_\varepsilon\|_\infty}{N}. \tag{3.23}$$

Recall that we work on the event A_N defined in (3.9). On this event, $D_N \cup \Delta_N$ contains a subset of the form $I \times I$ with $I \subset \{1, \dots, N\}$ and $|I| \geq (1-\eta)N$. Let such a random set be chosen, for definiteness we choose it minimally. We continue the estimation of (3.23) with

$$-\frac{1}{N\beta}K_{N,\beta}^{(N)} \leq -\frac{1}{2} \frac{\alpha_R(v) |I|^2}{N^2} \langle \bar{\mu}_{I,\beta} * \kappa_\varepsilon, \bar{\mu}_{I,\beta} * \kappa_\varepsilon \rangle + 2\xi \alpha_R(v) + \frac{1}{2} \frac{\alpha_R(v) \|\kappa_\varepsilon\|_\infty}{N}, \tag{3.24}$$

and from this the assertion follows. \square

Using Lemma 3.3 on the left hand side of (3.1), we obtain the following bound.

Corollary 3.4. *Fix $\varepsilon, \xi, \eta > 0$. Then, for any $R > 0$, as $N \rightarrow \infty$,*

$$\begin{aligned} & \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{A_N(\varepsilon, \xi, \eta)} \right] \leq e^{o(N)} e^{N[\eta\beta\|f\|_\infty + 2\xi\beta\alpha_R(v) + C\eta]} \\ & \times \mathbb{E} \left[\exp \left\{ -\beta \lfloor (1-\eta)N \rfloor \left(\langle W - f, \bar{\mu}_{\lfloor (1-\eta)N \rfloor, \beta} \rangle + \frac{1}{2} \alpha_R(v) (1-\eta) \|\bar{\mu}_{\lfloor (1-\eta)N \rfloor, \beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \right], \end{aligned} \quad (3.25)$$

where $C > 0$ is an absolute constant.

Proof. Since the trapping potential W is nonnegative, we easily estimate

$$-H_{N,\beta} = -\beta \sum_{i=1}^N \langle W, \mu_\beta^{(i)} \rangle \leq -\beta \sum_{i \in I} \langle W, \mu_\beta^{(i)} \rangle = -\beta |I| \langle W, \bar{\mu}_{I,\beta} \rangle. \quad (3.26)$$

Furthermore, it is easy to see that

$$N\beta \langle f, \bar{\mu}_{N,\beta} \rangle \leq \beta |I| \langle f, \bar{\mu}_{I,\beta} \rangle + N\eta\beta \|f\|_\infty. \quad (3.27)$$

Using these two estimates and (3.16) in the expectation on the left hand side of (3.1), we obtain

$$\begin{aligned} & \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{A_N(\varepsilon, \xi, \eta)} \right] \\ & \leq \mathbb{E} \left[\exp \left\{ -\beta |I| \left(\langle W - f, \bar{\mu}_{I,\beta} \rangle + \frac{1}{2} \alpha_R(v) (1-\eta) \|\bar{\mu}_{I,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \mathbb{1}_{A_N(\varepsilon, \xi, \eta)} \right] e^{NC_{\eta, \xi, R} + o(N)}, \end{aligned} \quad (3.28)$$

where

$$C_{\eta, \xi, R} = \eta\beta \|f\|_\infty + 2\xi\beta\alpha_R(v). \quad (3.29)$$

Now we sum over all possible values of the random set I and note that the distribution of $\bar{\mu}_{I,\beta}$ is equal to the one of $\bar{\mu}_{l,\beta} = \frac{1}{l} \sum_{i=1}^l \mu_\beta^{(i)}$. Hence we get

$$\begin{aligned} \text{l.h.s. of (3.28)} & \leq e^{NC_{\eta, \xi, R} + o(N)} \sum_{l=\lfloor (1-\eta)N \rfloor}^N \sum_{L \subset \{1, \dots, N\}: |L|=l} \\ & \mathbb{E} \left[\mathbb{1}_{I=L} \exp \left\{ -l\beta \left(\langle W - f, \bar{\mu}_{L,\beta} \rangle + \frac{1}{2} \alpha_R(v) (1-\eta) \|\bar{\mu}_{L,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \mathbb{1}_{A_N(\varepsilon, \xi, \eta)} \right] \\ & \leq e^{NC_{\eta, \xi, R} + o(N)} \sum_{l=\lfloor (1-\eta)N \rfloor}^N \binom{N}{l} \\ & \times \mathbb{E} \left[\exp \left\{ -l\beta \left(\langle W - f, \bar{\mu}_{l,\beta} \rangle + \frac{1}{2} \alpha_R(v) (1-\eta) \|\bar{\mu}_{l,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \right], \end{aligned} \quad (3.30)$$

It is clear that there is a $C > 0$ such that, for any $\eta > 0$ and any $l \in \{\lfloor (1-\eta)N \rfloor, \dots, N\}$ we can estimate $\binom{N}{l} \leq e^{C\eta N}$. In the exponent, estimate $l \geq \lfloor (1-\eta)N \rfloor$ where l is multiplied with a nonnegative factor, respectively estimate $l \langle f, \bar{\mu}_{l,\beta} \rangle \leq \lfloor (1-\eta)N \rfloor \langle f, \bar{\mu}_{l,\beta} \rangle + \eta N \|f\|_\infty$. The sum on l is estimated against N , which is absorbed in the term $e^{o(N)}$. \square

Now we use arguments from large deviation theory to identify the large- N rate of the right hand side of (3.25):

Lemma 3.5 (Large deviation rate). *For any $\varepsilon, \xi, \eta > 0$ and any $R > 0$,*

$$\begin{aligned} & \limsup_{N \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)}} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle} \mathbb{1}_{A_N(\varepsilon, \xi, \eta)} \right] \\ & \leq \eta \|f\|_\infty + 2\xi\alpha_R(v) + \frac{C\eta}{\beta} - (1-\eta)\chi_{\varepsilon, R, \eta}^{(\otimes)}(f), \end{aligned} \quad (3.31)$$

where

$$\chi_{\varepsilon,R,\eta}^{(\otimes)}(f) = \frac{1}{\beta} \inf_{\phi \in L^2(\mathbb{R}^d): \|\phi\|_2^2=1} \left\{ J_\beta(\phi^2) + \langle W - f, \phi^2 \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\phi^2 * \kappa_\varepsilon\|_2^2 \right\}. \quad (3.32)$$

Proof. On the right hand side of (3.25), we will apply Cramér's Theorem [DZ98, Th. 6.1.3] in combination with Varadhan's Lemma [DZ98, Lemma 4.3.6] for the mean $\bar{\mu}_{l,\beta}$ of normalised occupation measures. Let us explain what these theorems say and how we apply them. See the Appendix, Section 4.1 for a brief account on large deviation theory.

Note that $\mathcal{M}_1(\mathbb{R}^d)$ is a closed convex subset of the space of all finite signed measures, $\mathcal{M}(\mathbb{R}^d)$. The duality relation

$$(f, \nu) \in \mathcal{C}_b(\mathbb{R}^d) \times \mathcal{M}(\mathbb{R}^d) \mapsto \int_{\mathbb{R}^d} f(x) \nu(dx) \quad (3.33)$$

determines a representation of $\mathcal{M}(\mathbb{R}^d)^*$, the topological dual of $\mathcal{M}(\mathbb{R}^d)$, as $\mathcal{C}_b(\mathbb{R}^d)$. Clearly, the topology inherited by $\mathcal{M}_1(\mathbb{R}^d)$ from $\mathcal{M}(\mathbb{R}^d)$ is the weak topology, which is induced by the test integrals against all bounded continuous functions. $\mathcal{M}_1(\mathbb{R}^d)$ is a Polish space with the Lévy metric [DS01]. Thus, all the assumptions of [DZ98, Th. 6.1.3] are satisfied. Hence, $(\bar{\mu}_{l,\beta})_{l \in \mathbb{N}}$ satisfies a weak large deviation principle. The rate function is equal to the Legendre-Fenchel transform of the logarithmic moment generating function of $\mu_\beta^{(1)}$, that is, it is the function J_β defined in (1.5).

For any $M > 0$, the set

$$F_M = \{\mu \in \mathcal{M}_1(\mathbb{R}^d) : \langle W, \mu \rangle \leq M\}$$

is compact, as is easily derived with the help of Prohorov's Theorem, using that $\lim_{|x| \rightarrow \infty} W(x) = \infty$ and the lower semi continuity of the map $\mu \mapsto \langle W, \mu \rangle$ (see Assumption (W)).

We abbreviate $l = \lfloor (1-\eta)N \rfloor$ for a while. On the right hand side of (3.25), we insert $\mathbb{1}_{F_M}(\bar{\mu}_{l,\beta}) + \mathbb{1}_{F_M^c}(\bar{\mu}_{l,\beta})$. On the event $\{\bar{\mu}_{l,\beta} \in F_M^c\}$, we estimate the trap part, $\langle W, \bar{\mu}_{l,\beta} \rangle$, from below against M and use that the remaining terms in the exponential are bounded from below. Hence,

$$\begin{aligned} & \mathbb{E} \left[\exp \left\{ -l\beta \left(\langle W - f, \bar{\mu}_{l,\beta} \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\bar{\mu}_{l,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \right] \\ & \leq e^{-l\beta(M - \|f\|_\infty)} + \mathbb{E} \left[\exp \left\{ -l\beta \left(\langle W - f, \bar{\mu}_{l,\beta} \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\bar{\mu}_{l,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \mathbb{1}_{F_M}(\bar{\mu}_{l,\beta}) \right]. \end{aligned} \quad (3.34)$$

The functional $\mu \mapsto \langle W - f, \mu \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\mu * \kappa_\varepsilon\|_2^2$ is lower semi continuous, as is easily seen from Fatou's lemma, and bounded from below. Furthermore, according to [DZ98, Th. 4.5.3], the family $(\bar{\mu}_{l,\beta})_{l \in \mathbb{N}}$ satisfies the upper bound in the weak large deviation principle with rate function J_β . Hence, we may apply the upper-bound part of Varadhan's lemma [DZ98, Lemma 4.3.6] to the right-hand side of (3.34), to obtain, if M is sufficiently large,

$$\begin{aligned} & \limsup_{l \rightarrow \infty} \frac{1}{l\beta} \log \mathbb{E} \left[\exp \left\{ -l\beta \left(\langle W - f, \bar{\mu}_{l,\beta} \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\bar{\mu}_{l,\beta} * \kappa_\varepsilon\|_2^2 \right) \right\} \right] \\ & \leq - \inf_{\nu \in F_M} \left(J_\beta(\nu) + \langle W - f, \nu \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\nu * \kappa_\varepsilon\|_2^2 \right). \end{aligned} \quad (3.35)$$

Lemma 2.2 implies that the infimum on the right hand side is equal to $\chi_{\varepsilon,R,\eta}^{(\otimes)}(f)$. \square

Summarising the contributions from A_N and A_N^c , we obtain the following.

Corollary 3.6.

$$\limsup_{N \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)} e^{N \langle f, \bar{\mu}_{N,\beta} \rangle}} \right] \leq - \liminf_{\eta \downarrow 0} \liminf_{R \rightarrow \infty} \liminf_{\varepsilon \downarrow 0} \chi_{\varepsilon,R,\eta}^{(\otimes)}(f), \quad (3.36)$$

where $\chi_{\varepsilon,R,\eta}^{(\otimes)}(f)$ is defined in (3.32).

Proof. A combination of Lemmas 3.2 and 3.5 gives that the left hand side of (3.36) is not smaller than

$$\eta \|f\|_\infty + 2\xi \alpha_R(v) + \frac{C\eta}{\beta} - (1-\eta) \liminf_{\varepsilon \downarrow 0} \chi_{\varepsilon, R, \eta}^{(\otimes)}(f),$$

for any $\eta, R, \xi > 0$. Letting $\eta, \xi \downarrow 0$ and $R \rightarrow \infty$, we arrive at the assertion. \square

Now we identify the right hand side of (3.36):

Lemma 3.7 (Approximating the variational formula).

$$\liminf_{\eta \downarrow 0} \liminf_{R \rightarrow \infty} \liminf_{\varepsilon \downarrow 0} \chi_{\varepsilon, R, \eta}^{(\otimes)}(f) \geq \chi^{(\otimes)}(f), \quad (3.37)$$

where $\chi^{(\otimes)}(f)$ is defined in (3.1).

Proof. We first fix $\eta > 0$ and $R >$ and prove that

$$\liminf_{\varepsilon \downarrow 0} \chi_{\varepsilon, R, \eta}^{(\otimes)}(f) \geq \chi_{R, \eta}^{(\otimes)}, \quad (3.38)$$

with

$$\chi_{R, \eta}^{(\otimes)}(f) = \frac{1}{\beta} \inf_{\phi \in L^2(\mathbb{R}^d): \|\phi\|_2=1} \left(J_\beta(\phi^2) + \langle W - f, \phi^2 \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\phi\|_4^4 \right). \quad (3.39)$$

Let $(\phi_\varepsilon)_{\varepsilon \geq 0}$ be an approximate minimising sequence for the right hand side of (3.39), i.e.,

$$\liminf_{\varepsilon \searrow 0} \frac{1}{\beta} \left(J_\beta(\phi_\varepsilon^2) + \langle W - f, \phi_\varepsilon^2 \rangle + \frac{1}{2} \alpha_R(v)(1-\eta) \|\phi_\varepsilon^2 * \kappa_\varepsilon\|_2^2 \right) = \liminf_{\varepsilon \searrow 0} \chi_{\varepsilon, R, \eta}^{(\otimes)}(f).$$

In particular, $(J_\beta(\phi_\varepsilon^2))_{\varepsilon \geq 0}$, $(\langle W - f, \phi_\varepsilon \rangle)_{\varepsilon \geq 0}$ and $(\|\phi_\varepsilon^2 * \kappa_\varepsilon\|_2^2)_{\varepsilon \geq 0}$ are bounded. As $\varepsilon \downarrow 0$, along suitable subsequences, the probability measures $\mu_\varepsilon(dx) = \phi_\varepsilon^2(x) dx$ converge weakly to a probability measure $\mu(dx)$. Certainly, we may assume that $\chi_{\varepsilon, R, \eta}^{(\otimes)}(f)$ is bounded as $\varepsilon \downarrow 0$, and therefore also $J_\beta(\phi_\varepsilon^2)$ is. The lower semi continuity of J_β with respect to the weak topology of probability measures gives that $J_\beta(\mu) \leq \liminf_{\varepsilon \searrow 0} J_\beta(\mu_\varepsilon) < \infty$. From Lemma 2.2 we get the existence of a density for the measure μ , i.e., $\mu(dx) = \phi^2(x) dx$ for some $\phi^2 \in L^2(\mathbb{R}^d)$ satisfying $\|\phi\|_2 = 1$. Since $\varepsilon \mapsto \|\phi_\varepsilon^2 * \kappa_\varepsilon\|_2$ is bounded, there is a function $\psi \in L^4(\mathbb{R}^d)$ such that, along suitable subsequences, $\phi_\varepsilon^2 * \kappa_\varepsilon$ converges weakly in $L^2(\mathbb{R}^d)$ to ψ^2 , and $\|\psi\|_4^4 \leq \liminf_{\varepsilon \downarrow 0} \|\phi_\varepsilon^2 * \kappa_\varepsilon\|_2^2$. Thus, for every $g \in C_c(\mathbb{R}^d)$ we get

$$|\langle g, \phi^2 - \psi^2 \rangle| \leq |\langle g, \phi^2 \rangle - \langle g, \phi_\varepsilon^2 \rangle| + |\langle g, \phi_\varepsilon^2 \rangle - \langle g, \phi_\varepsilon^2 * \kappa_\varepsilon \rangle| + |\langle g, \phi_\varepsilon^2 * \kappa_\varepsilon - \psi^2 \rangle|. \quad (3.40)$$

Now, the first term on the right hand side of (3.40) vanishes in the limit $\varepsilon \rightarrow 0$ because g is bounded and continuous and the convergence follows from the weak convergence of the probability measures. The second term on the right hand side of (3.40) is estimated as

$$|\langle g, \phi_\varepsilon^2 \rangle - \langle g, \phi_\varepsilon^2 * \kappa_\varepsilon \rangle| = |\langle g - g * \kappa_\varepsilon, \phi_\varepsilon^2 \rangle| \leq \|g - g * \kappa_\varepsilon\|_\infty \rightarrow 0 \text{ for } \varepsilon \rightarrow 0, \quad (3.41)$$

since $g \in C_c(\mathbb{R}^d)$. The last term on the right hand side of (3.40) vanishes in the limit $\varepsilon \rightarrow 0$ because $g \in L^2(\mathbb{R}^d)$. Hence, $\langle g, \phi^2 \rangle = \langle g, \psi^2 \rangle$ and therefore $\phi = \psi$ almost everywhere. Clearly, $\liminf_{\varepsilon \downarrow 0} \langle W, \phi_\varepsilon^2 \rangle \geq \langle W, \phi^2 \rangle$. Altogether, (3.38) follows.

We now finish the proof of the lemma by showing that

$$\liminf_{\eta \downarrow 0} \liminf_{R \rightarrow \infty} \chi_{R, \eta}^{(\otimes)}(f) \geq \chi^{(\otimes)}(f). \quad (3.42)$$

Since the map $x \mapsto v(|x|)$ is assumed integrable, it is clear that, as $R \rightarrow \infty$, $\alpha_R(v)$ converges towards $\alpha(v)$ defined in (1.9). Hence, the proof of (3.42) is an easy task, and we omit it. \square

3.3 Proof of the lower bound of (3.1) in Proposition 3.1

Now we turn to the proof of the lower bound in (3.1). We were not able to produce a proof along the lines of usual large deviation arguments including Cramér's Theorem and Varadhan's Lemma, since we did not find any way to overcome the technical difficulties stemming from the singularity of the pair interaction term. Instead, we write the expectation on the left-hand side of (3.1) as N iterated expectations over the N Brownian motions and use a lower estimate that is directly implied by the definition of the rate function, J_β , more precisely, of some variant to be introduced below. In order to explain this idea, fix $\phi \in L^2(\mathbb{R}^d)$ and consider the random potential

$$q_j := - \sum_{i=1}^{j-1} V_N * \mu_\beta^{(i)} - (N-j)V_N * \phi^2, \quad j = 1, \dots, N. \quad (3.43)$$

Here we used the notation $V * \mu(x) = \int_{\mathbb{R}^d} v(|x-y|) \mu(dy)$ (analogously with ϕ^2 , conceived as a finite measure) and an analogous notation for V_N with v replaced by $v_N(\cdot) = N^{d-1}v(\cdot/N)$. We rewrite the left-hand side of (3.1) as follows. We write $\mathbb{E}^{(i)}$ for the expectation with respect to the i -th Brownian motion. Recalling the definition of $K_{N,\beta}^{(N)}$ in (1.4) and noting that $q_N = - \sum_{i < N} V_N * \mu_\beta^{(i)}$, we see that we have

$$\begin{aligned} \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)} + \beta N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] &= \mathbb{E}^{(1)} \otimes \dots \otimes \mathbb{E}^{(N-1)} \left[e^{-H_{N-1,\beta} - K_{N-1,\beta}^{(N)} + \beta(N-1) \langle f, \bar{\mu}_{N-1,\beta} \rangle} \right. \\ &\quad \left. \times \mathbb{E}^{(N)} \left[e^{\beta \langle q_N - W + f, \mu_\beta^{(N)} \rangle} \right] \right]. \end{aligned} \quad (3.44)$$

The main idea in our proof of the lower bound is that the definition of J_β directly implies the estimate

$$\mathbb{E} \left[e^{\beta \langle h, \mu_\beta \rangle} \right] \geq e^{-\beta J_\beta(\phi^2) + \beta \langle h, \phi^2 \rangle}, \quad h \in \mathcal{C}_b(\mathbb{R}^d), \phi \in L^2(\mathbb{R}^d), \|\phi\|_2 = 1. \quad (3.45)$$

If the random potential $h = q_N - W + f$ were in $\mathcal{C}_b(\mathbb{R}^d)$ almost surely, then (3.45) instantly implied an estimate for the last term on the right hand side of (3.44), and we could choose ϕ arbitrary and optimise later on ϕ .

However, the random potential $h = q_N - W + f$ does not have sufficient regularity for applying (3.45) directly. But note that q_j lies in $L^2(\mathbb{R}^d)$ almost surely, as is easily derived from the assumption that $\int_{\mathbb{R}^d} v(|x|)^2 dx < \infty$. In order to make (3.45) applicable for functions h of the form $q - W + f$ with $q \in L^2(\mathbb{R}^d)$, we have to establish a lower bound for J_β in terms of a supremum over this class of potentials. This is the content of the following lemma.

Lemma 3.8. *For any $\phi \in L^2(\mathbb{R}^d) \cap L^4(\mathbb{R}^d)$ satisfying $\|\phi\|_2 = 1$,*

$$J_\beta(\phi^2) \geq \sup_{h \in L^2(\mathbb{R}^d): h \leq 0} \left(\langle -W + h, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E} \left[e^{\beta \langle -W + h, \mu_\beta \rangle} \right] \right). \quad (3.46)$$

Proof. As a first step, we show that

$$J_\beta(\phi^2) \geq \sup_{f \in L^2(\mathbb{R}^d): f \leq 0} \left(\langle f, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E} \left[e^{\beta \langle f, \mu_\beta \rangle} \right] \right). \quad (3.47)$$

Let $f \in L^2(\mathbb{R}^d)$ be given satisfying $f \leq 0$. We approximate f by continuous bounded functions in a standard way as follows. Let $\kappa: \mathbb{R}^d \rightarrow [0, \infty)$ smooth with $\int_{\mathbb{R}^d} \kappa(x) dx = 1$ and $\text{supp } \kappa \subset [-1, 1]^d$. Fix $\varepsilon > 0$ and consider $f_\varepsilon = f * \kappa_\varepsilon$, where $\kappa_\varepsilon(x) = \varepsilon^{-d} \kappa(x/\varepsilon)$ for $x \in \mathbb{R}^d$. Then f_ε is continuous. Using Schwarz' inequality and the fact that $f \in L^2(\mathbb{R}^d)$, one sees that f_ε is bounded. Furthermore,

$$\liminf_{\varepsilon \rightarrow 0} \langle f_\varepsilon, \phi^2 \rangle = \liminf_{\varepsilon \rightarrow 0} \langle f, \phi^2 * \kappa_\varepsilon \rangle = \langle f, \phi^2 \rangle, \quad (3.48)$$

since $f \in L^2(\mathbb{R}^d)$ and $\phi^2 \in L^2(\mathbb{R}^d)$.

Since $f_\varepsilon \rightarrow f$ strongly in L^2 , we can pick a subsequence $\varepsilon_n \downarrow 0$ such that $f_{\varepsilon_n} \rightarrow f$ pointwise almost everywhere. Since $f \leq 0$, it follows from the bounded convergence theorem that

$$\lim_{n \rightarrow \infty} \mathbb{E} \left[e^{\int_0^\beta f_{\varepsilon_n}(B_s) ds} \right] = \mathbb{E} \left[e^{\int_0^\beta f(B_s) ds} \right]. \quad (3.49)$$

From this, together with (3.48), (3.47) follows.

Now we prove (3.46) by showing that

$$\sup_{f \in L^2(\mathbb{R}^d): f \leq 0} \left(\langle f, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E} \left[e^{\beta \langle f, \mu_\beta \rangle} \right] \right) \geq \sup_{h \in L^2(\mathbb{R}^d): h \leq 0} \left(\langle -W + h, \phi^2 \rangle - \frac{1}{\beta} \log \mathbb{E} \left[e^{\beta \langle -W + h, \mu_\beta \rangle} \right] \right).$$

This is similar to the proof of ‘ \geq ’ in (2.2) in Lemma 2.3. Let $h \in L^2(\mathbb{R}^d)$ satisfy $h \leq 0$, and consider $f_R := (-W + h)\mathbb{1}_{Q_R}$ for $R > 0$. Clearly, $f_R \in L^2(\mathbb{R}^d)$ with $f_R \leq 0$, and $f_R \downarrow -W + h$ pointwise as $R \rightarrow \infty$. Therefore,

$$\liminf_{R \rightarrow \infty} \langle f_R, \phi^2 \rangle \geq \langle -W + h, \phi^2 \rangle,$$

according to the monotonous convergence theorem. Furthermore, for the same reason, and since $-W + h$ is bounded from above,

$$\limsup_{R \rightarrow \infty} \mathbb{E} \left[e^{\beta \langle f_R, \mu_\beta \rangle} \right] \leq \mathbb{E} \left[e^{\beta \langle -W + h, \mu_\beta \rangle} \right].$$

This implies the statement and finishes the proof of (3.46). \square

We would like to remark that it is the assertion in (3.48) that forces us to require that $v \circ |\cdot|$ lies in $L^2(\mathbb{R}^d)$, since we will apply Lemma 3.8 to the minimiser ϕ^2 on the right-hand side of (3.2), and we do not know any higher integrability property of this function than that $\phi^2 \in L^2(\mathbb{R}^d)$.

It is clear that (3.46) remains true if W is replaced by $W - f$, where $f \in \mathcal{C}_b(\mathbb{R}^d)$, since adding a constant to $W - f$ does not change the value of the expression in the supremum on the right-hand side of (3.46), and the potential $W - f - \inf f$ also satisfies Assumption (W).

Now we proceed with the proof of the lower bound of (3.1) in Proposition 3.1. Go back to (3.44) and recall that the random potential q_j defined in (3.43) is nonpositive and lies in $L^2(\mathbb{R}^d)$. Using Lemma 3.8 with $h = q_N$ and W replaced by $W - f$, the last term on the right hand side of (3.44) is estimated as follows. For any $\phi \in L^2(\mathbb{R}^d) \cap L^4(\mathbb{R}^d)$ satisfying $\|\phi\|_2 = 1$,

$$\mathbb{E}^{(N)} \left[e^{\beta \langle q_N - W + f, \mu_\beta^{(N)} \rangle} \right] \geq e^{-\beta J_\beta(\phi^2) + \beta \langle q_N - W + f, \phi^2 \rangle}. \quad (3.50)$$

Using this in (3.44), we obtain

$$\begin{aligned} \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)} + \beta N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] &\geq \mathbb{E}^{(1)} \otimes \dots \otimes \mathbb{E}^{(N-2)} \left[e^{-H_{N-2,\beta} - K_{N-2,\beta} + \beta \langle f, \mu_{N-2,\beta} \rangle} \right] \\ &\mathbb{E}^{(N-1)} \left[e^{\beta \langle q_{N-1} - W + f, \mu_\beta^{(N-1)} \rangle} \right] \times e^{-\beta J_\beta(\phi^2) - \beta \langle W - f, \phi^2 \rangle - \beta \langle V_N * \phi^2, \phi^2 \rangle}. \end{aligned} \quad (3.51)$$

Now we apply the same reasoning to the last expectation and iterate the argument. In this way we derive

$$\frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)} + \beta N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] \geq -J_\beta(\phi^2) - \langle W - f, \phi^2 \rangle - \frac{N-1}{2} \langle V_N * \phi^2, \phi^2 \rangle. \quad (3.52)$$

Since $v \circ |\cdot|$ lies in $L^1(\mathbb{R}^d)$ by assumption and since $\phi^2 \in L^2(\mathbb{R}^d)$, we have that

$$\lim_{N \rightarrow \infty} (N-1) V_N * \phi^2 = \phi^2 \int_{\mathbb{R}^d} v(|x|) dx = \phi^2 \frac{1}{2} \alpha(v) \quad \text{strongly in } L^2(\mathbb{R}^d).$$

Hence,

$$\lim_{N \rightarrow \infty} \frac{N-1}{2} \langle V_N * \phi^2, \phi^2 \rangle = \frac{1}{2} \alpha(v) \|\phi\|_4^4. \quad (3.53)$$

This implies that

$$\begin{aligned} \liminf_{N \rightarrow \infty} \frac{1}{N\beta} \log \mathbb{E} \left[e^{-H_{N,\beta} - K_{N,\beta}^{(N)} + \beta N \langle f, \bar{\mu}_{N,\beta} \rangle} \right] &\geq -J_\beta(\phi^2) - \langle W - f, \phi^2 \rangle - \frac{1}{2} \alpha(v) \|\phi\|_4^4 \\ &\geq -\chi_{\alpha(v)}^{(\otimes)}(f), \end{aligned} \quad (3.54)$$

and the proof of the lower bound in (3.1) is finished. \square

4. APPENDIX

4.1 Large deviations.

For the convenience of our reader, we repeat the notion of a large-deviation principle and of the most important facts that are used in the present paper. See [DZ98] for a comprehensive treatment of this theory.

Let \mathcal{X} denote a topological vector space. A lower semi-continuous function $I: \mathcal{X} \rightarrow [0, \infty]$ is called a *rate function* if I is not identical ∞ and has compact level sets, i.e., if $I^{-1}([0, c]) = \{x \in \mathcal{X} : I(x) \leq c\}$ is compact for any $c \geq 0$. A sequence $(X_N)_{N \in \mathbb{N}}$ of \mathcal{X} -valued random variables X_N satisfies the *large-deviation upper bound* with *speed* a_N and rate function I if, for any closed subset F of \mathcal{X} ,

$$\limsup_{N \rightarrow \infty} \frac{1}{a_N} \log \mathbb{P}(X_N \in F) \leq - \inf_{x \in F} I(x), \quad (4.1)$$

and it satisfies the *large-deviation lower bound* if, for any open subset G of \mathcal{X} ,

$$\liminf_{N \rightarrow \infty} \frac{1}{a_N} \log \mathbb{P}(X_N \in G) \geq - \inf_{x \in G} I(x). \quad (4.2)$$

If both, upper and lower bound, are satisfied, one says that $(X_N)_N$ satisfies a *large-deviation principle*. The principle is called *weak* if the upper bound in (4.1) holds only for *compact* sets F . A weak principle can be strengthened to a full one by showing that the sequence of distributions of X_N is *exponentially tight*, i.e., if for any $M > 0$ there is a compact subset K_M of \mathcal{X} such that $\mathbb{P}(X_N \in M^c) \leq e^{-MN}$ for any $n \in \mathbb{N}$.

One of the most important conclusions from a large deviation principle is *Varadhan's Lemma*, which says that, for any bounded and continuous function $F: \mathcal{X} \rightarrow \mathbb{R}$,

$$\lim_{N \rightarrow \infty} \frac{1}{N} \log \int e^{NF(X_N)} d\mathbb{P} = - \inf_{x \in \mathcal{X}} (I(x) - F(x)).$$

All the above is usually stated for probability measures \mathbb{P} only, but the notion easily extends to *sub-probability* measures $\mathbb{P} = \mathbb{P}_N$ depending on N . Indeed, first observe that the situation is not changed if \mathbb{P} depends on N , since a large deviation principle depends only on distributions. Furthermore, the connection between probability distributions $\tilde{\mathbb{P}}_N$ and sub-probability measures \mathbb{P}_N is provided by the transformed measure $\tilde{\mathbb{P}}_N(X_N \in A) = \mathbb{P}_N(X_N \in A) / \mathbb{P}_N(X_N \in \mathcal{X})$: If the measures $\mathbb{P}_N \circ X_N^{-1}$ satisfy a large deviation principle with rate function I , then the probability measures $\tilde{\mathbb{P}}_N \circ X_N^{-1}$ satisfy a large deviation principle with rate function $I - \inf I$.

One standard situation in which a large deviation principle holds is the case where \mathbb{P} is a probability measure, and $X_N = \frac{1}{N}(Y_1 + \dots + Y_N)$ is the mean of N i.i.d. \mathcal{X} -valued random variables Y_i whose moment generating function $M(F) = \int e^{F(Y_1)} d\mathbb{P}$ is finite for all elements F of the topological dual space \mathcal{X}^* of \mathcal{X} . In this case, the abstract *Cramér Theorem* provides a weak large deviation principle for $(X_N)_{N \in \mathbb{N}}$ with rate function equal to the Legendre-Fenchel transform of $\log M$, i.e., $I(x) = \sup_{F \in \mathcal{X}^*} (F(x) - \log M(F))$.

4.2 Gross-Pitaevskii theory.

Consider the ground-state energy per particle of the Hamilton operator H_N in (1.14),

$$\chi_N = \frac{1}{N} \inf_{h \in H^1(\mathbb{R}^{dN}): \|h\|_2=1} \langle h, H_N h \rangle. \quad (4.3)$$

It is standard to show the existence, uniqueness and some regularity properties of the minimiser $h_N \in H^1(\mathbb{R}^{dN})$. The large- N behaviour, in a certain dilute regime, of χ_N and of the minimiser h_N was studied by Lieb *et al.* in a series of papers [LSY00], [LY01], [LSY01], [LS02], see also the monograph [LSSY05]. It turned out there that the Gross-Pitaevskii formula in (1.15) well approximates the ground-state energy. A summary of the large- N results for χ_N is as follows. Assume that $d \in \{2, 3\}$, that $v \geq 0$ with $v(0) \in (0, \infty]$, and $\int_{a+1}^{\infty} v(r)r^{d-1} dr < \infty$, where $a = \inf\{r > 0: v(r) < \infty\} \in [0, \infty)$. These assumptions guarantee that the *scattering length*, denoted by $\tilde{\alpha}(v)$, is finite ([LSSY05]). Note, that $\alpha(v) > \tilde{\alpha}(v)$ ([ABK06]).

Theorem 4.1 (Large- N asymptotic of χ_N in $d \in \{2, 3\}$, [LSY00], [LY01], [LSY01]). *Replace v by $v_N(\cdot) = \beta_N^{-2}v(\cdot\beta_N^{-1})$ with $\beta_N = 1/N$ in $d = 3$ and $\beta_N^2 = \tilde{\alpha}(v)^{-2}e^{-N/\tilde{\alpha}(v)}N\|\phi_{\tilde{\alpha}(v)}^{(\text{GP})}\|_4^{-4}$ in $d = 2$. Define $\phi_N^2 \in H^1(\mathbb{R}^d)$ as the normalised first marginal of h_N^2 , i.e.,*

$$\phi_N^2(x) = \int_{\mathbb{R}^{d(N-1)}} h_N^2(x, x_2, \dots, x_N) dx_2 \cdots dx_N, \quad x \in \mathbb{R}^d.$$

Then

$$\lim_{N \rightarrow \infty} \chi_N = \chi_{\tilde{\alpha}(v)}^{(\text{GP})} \quad \text{and} \quad \phi_N^2 \rightarrow (\phi_{\tilde{\alpha}(v)}^{(\text{GP})})^2 \quad \text{in weak } L^1(\mathbb{R}^d)\text{-sense.}$$

The proofs show that the ground state, h_N , approaches the product-state $(\phi_{\tilde{\alpha}(v)}^{(\text{GP})})^{\otimes N}$ if N gets large.

Moreover, on the basis of this result, the occurrence of Bose-Einstein condensation in the ground-state (zero-temperature) was proved in [LS02].
