Abstract

The paper is concerned with the problem of testing a linear hypothesis about regression function. We propose a new testing procedure based on the Haar transform which is adaptive to unknown smoothness properties of the underlying function. The results describe optimality properties of this procedure under mild conditions on the model.

1 Introduction

Suppose we are given data \((X_i, Y_i), i = 1, \ldots, n,\) with \(X_i \in \mathbb{R}^1, Y_i \in \mathbb{R}^1,\) obeying the regression equation

\[ Y_i = f(X_i) + \xi_i \]

where \(f\) is an unknown regression function and \(\xi_i\) are zero mean random errors. Statistical analysis for such models may focus on the qualitative features of the underlying function \(f.\) Particularly, no-response model corresponds to testing the simple zero hypothesis that \(f\) is a constant function. Another typical example is connected to the hypothesis of linearity. More generally one may consider a parametric type hypothesis
about $f$. In this paper, we restrict ourselves to the case of the hypothesis of linearity. Using the hypothesis testing framework, we test the null hypothesis $H_0 : f \text{ 'is linear'},$ that is, $f(x) = a + bx$ for some constants $a, b,$ versus the alternative $H_1 : f \text{ 'is not linear'}.$

The problem of testing a simple or parametrically specified hypothesis is one of the classical in statistical inference, see e.g. Neyman (1937), Mann and Wald (1942), Lehmann (1957). Let $\phi$ be a test i.e. a measurable function of the observations $Y_1, \ldots, Y_n$ with two values 0, 1. As usual, the event $\{\phi = 0\}$ is treated as accepting the hypothesis and $\phi = 1$ means that the hypothesis is rejected. The quality of a test $\phi$ is described in terms of the corresponding error probabilities of the first and second kinds. Let $P_f$ denote the distribution of the data $Y_1, \ldots, Y_n$ for a fixed model function $f$, see (1.1). If $f$ coincides with a linear function $f_0$, then the error probability of the first kind at the point $f_0$ is the probability under $f_0$ to reject the hypothesis,

$$\alpha_{f_0}(\phi) = P_{f_0}(\phi = 1).$$

Similarly one defines the error probability $\beta_f(\phi)$ of the second kind. If the function $f$ is not linear, then

$$\beta_f(\phi) = P_f(\phi = 0).$$

Typically one aims to construct a test $\varphi$ of the prescribed level $\alpha_0$, that is, satisfying for a given $\alpha_0 > 0$ the condition $\alpha_{f_0}(\phi) \leq \alpha_0$ which also has a nontrivial power $1 - \beta_f(\varphi) > 0$ against a possibly large class of alternatives $f$. A large number of proposals for constructing such tests can be found in the literature. We refer to Hart (1997) where the reader can find historical remarks and further references. Note meanwhile, that the majority of results in this domain is concentrated either only on verifying the condition $\alpha_{f_0}(\phi) \leq \alpha_0$ or on studying asymptotic properties of the power function $1 - \beta_f(\phi)$ for a fixed or local alternative. The local alternative approach assumes that the hypothesis is tested versus alternatives approaching the null hypothesis from a specific direction. Many tests have been shown to have nontrivial asymptotic power against every such local alternative, see e.g. Bierens (1982, 1990), Eubank and Spiegelman (1990), Andrews (1997), Stute (1997) among others. However, it turns out that the finite sample power of the proposed tests is not uniform with respect to the direction of the alternative: some of directional alternatives can be detected easily, the others require a huge sample size. Moreover, Burnashev (1979) and Ingster (1982) have shown that no test can be uniformly powerful against all the local alternatives. This leads to considering the uniform power of the test over a large class $\mathcal{F}$ of alternatives, so that $\beta_f(\varphi) \leq \beta_0$ with some $\beta_0 < 1 - \alpha_0$ uniformly over $f \in \mathcal{F}$. Following Ingster (1982, 1993), we consider the class $\mathcal{F}(\rho)$
consisting of smooth (in some sense) alternatives which are also separated from the set of linear functions with the distance $\rho$, that is,

$$\inf_{a,b} \| f(\cdot) - a - b \cdot \| \geq \rho, \quad (1.2)$$

$\| \cdot \|$ being the usual $L_2$-norm. Then the quality of a test $\varphi$ of the level $\alpha_0$ can be measured by a minimal separation distance $\rho$ such that $\beta_f(\varphi) \leq \beta_0$ for all $f$ from $\mathcal{F}(\rho)$. A test $\phi^*$ with the level $\alpha_0$ is optimal if it minimizes the corresponding value $\rho$. Under this approach, the goal is both to evaluate the minimal possible separation distance $\rho$ and to describe the corresponding optimal tests.

It turns out that the structure of optimal tests and the corresponding separation distance strongly depend on the smoothness class $\mathcal{F}$ we consider. Ingster (1982, 1993) described the optimal rate of decay of the separation distance $\rho$ to zero as the sample size $n$ tends to infinity for Hölder and Sobolev function classes, the case of Besov classes is considered in Lepski and Spokoiny (1999) and Spokoiny (1998). Sharp optimal asymptotic results can be found in Ermakov (1990), Lepski and Tsybakov (1996), Ingster and Suslina (1998).

Unfortunately all the mentioned procedures hardly apply in practice since the information about smoothness properties of the underlying function $f$ is typically lacking. Some adaptive (data-driven) smooth tests are proposed in Eubank and Hart (1992), Ledwina (1994), Fan (1996), Hart (1997) where the reader can found further references. Spokoiny (1996, 1998) considered the problem of adaptive testing against a smooth alternative and constructed an adaptive test which is near optimal by a log log multiple for a wide range of smoothness classes. Moreover, the test of Spokoiny (1996) is rate optimal in the class of adaptive tests, that is, this log log factor is an unavoidable payment for the adaptive property. The inconvenience for practical applications is that this procedure is designed for an idealized ‘signal + white noise’ model and only the case of a simple null is considered.

The aim of this paper is to develop an adaptive testing method which does not require a regular design, allow to proceed with non-Gaussian errors with an unknown distribution and with a non-simple null, and which is computationally simple and stable w.r.t. the design non-regularity. The latter property is achieved by making use of the simplest wavelet basis, namely the Haar transform. It is worth mentioning that the Haar basis is not often used for estimating the regression function $f$ from (1.1) because of its non-regularity: the corresponding estimator is based on the piecewise constant approximation of the underlying function and it is only rate suboptimal. Nevertheless, Ingster (1993) has constructed a $\chi^2$-test (also based on a piecewise constant approximation) which
provides the optimal testing rate in the ‘signal + white noise’ framework. Here his construction is extended to the case of testing the linear hypothesis for regression with unknown smoothness properties and with a deterministic non-regular design.

Another remark concerns the assumption on the errors $\xi_i$. Assuming i.i.d. errors with a known distribution, one can easily select a critical level for any test statistic using the Monte-Carlo or other resampling technique. For practical applications, this approach needs to be justified since the underlying error distribution is typically unknown. The problem becomes even more complicated if a data-driven test basing on the maximum of different test statistics is used. We establish some general results on the approximation of quadratic forms of independent random variables by similar quadratic forms of Gaussian random variables which help to justify the following recipe: if the critical level of the considered test statistic is calculated for Gaussian errors, then it applies, at least asymptotically, as the sample size grows, for an arbitrary errors distribution with bounded 6 moments.

The paper is organized as follows. Section 2 contains the description of the proposed testing procedure. The properties of this procedure are discussed in Section 3. The proofs are postponed to Section 4. In the Appendix we collect some general results for quadratic forms.

2 Testing procedure

We consider the univariate regression model

$$Y_i = f(X_i) + \xi_i, \quad i = 1, \ldots, n,$$

with additive homogeneous noise, that is, the errors $\xi_i$ are independent identically distributed with zero mean and the variance $\sigma^2$: $E\xi_i = 0$ and $E\xi_i^2 = \sigma^2$. The design points $X_1, \ldots, X_n$ are assumed to be rescaled to the interval $[0,1]$, that is, $X_i \in [0,1]$ for all $i = 1, \ldots, n$.

The proposed test makes use of the Haar transform. We first recall some useful facts about the Haar decomposition and then explain the idea of the method.

2.1 Preliminaries

Hereafter we denote by $I$ the multi-index $I = (j,k)$ with $j = 0, 1, 2, \ldots$ and $k = 0, 1, \ldots, 2^j - 1$, and let $\mathcal{I}$ be the set of all such multi-indices. We also set

$$\mathcal{I}_j = \{(j,k), k = 0, 1, \ldots, 2^j - 1\}$$
for the index set corresponding to \( j \)-th level. Let now the function \( \psi(t) \) be defined by

\[
\psi(t) = \begin{cases} 
0 & t < 0, \\
1 & 0 \leq t < 1/2, \\
-1 & 1/2 \leq t < 1, \\
0 & t \geq 1.
\end{cases}
\] (2.2)

For every \( I = (j, k) \), define the Haar basis function \( h_I \) by

\[
h_I(t) = 2^{j/2} \psi(2^j t - k). \] (2.3)

Clearly the function \( h_I \) is supported on the interval \( A_I = [2^{-j} k, 2^{-j}(k + 1)] \). It is well known that each measurable square integrable function \( f \) on \([0, 1]\) can be decomposed in the following way

\[
f(t) = c_0 + \sum_{I \in \mathcal{I}} c_I h_I(t) = c_0 + \sum_{j=0}^{\infty} \sum_{I \in \mathcal{I}_j} c_I h_I(t). \] (2.4)

This means that the problem of recovering the function \( f \) can be transformed into the problem of estimating the coefficients \( c_I \) by given data. Since we have only \( n \) observations, it makes no sense to estimate more (in order) than \( n \) coefficients. We restrict therefore the total number of considered levels \( j \). Let some \( j \) be fixed such that \( 2^{j+1} < n \). We also introduce the rescaled basis functions \( \psi_I \) to provide \( \sum_i |\psi_I(X_i)|^2 = 1 \), that is,

\[
\psi_I(X_i) = \mu_I^{-1} h_I(X_i),
\]

with \( \mu_I^2 = \sum_{i=1}^n h_I^2(X_i) \). We suppose here that \( \mu_I \) is strictly positive. Otherwise we set \( \psi_I \equiv 0 \). Next we replace the infinite decomposition (2.4) by the finite approximation \( \sum_{I \in \mathcal{I}(j)} c_I \psi_I(t) \) where the index set \( \mathcal{I}(j) \) contains all level sets \( \mathcal{I}_\ell \) with \( \ell \leq j \). Taking into account the structure of the null hypothesis, we complement the set of functions \((\psi_I, I \in \mathcal{I}_\ell), \ell \leq j \), with two functions \( \psi_0 \equiv n^{-1/2} \) and \( \psi_1(t) = t \left( \sum_{i=1}^n X_i^2 \right)^{-1/2} \), that is, we consider the set of indices

\[
\mathcal{I}(j) = \{0, 1\} + \bigcup_{\ell=0}^j \mathcal{I}_\ell. \] (2.5)

The idea of the proposed procedure is to estimate all the coefficients \( (c_I, I \in \mathcal{I}(j)) \) from the data \( Y_1, \ldots, Y_n \) and then to test that all the coefficients \( c_I \) for \( I \neq 0, 1 \) are zero.

For a function \( g \), define \( \|g\|_n \) by

\[
\|g\|_n^2 = \sum_{i=1}^n g_i^2(X_i).
\]
Define also the column-vector \( \theta^*(j) = (\theta_I^*, I \in \mathcal{I}(j)) \) as a minimizer of the error of approximating \( f \) by a linear combination of \( \psi_I, I \in \mathcal{I}(j) \):

\[
\theta^*(j) = \underset{\theta(j)}{\operatorname{argmin}} \| f - \sum_{I \in \mathcal{I}(j)} \theta_I \psi_I \|_n^2.
\] (2.6)

This is a quadratic optimization problem with respect to the coefficients \( \{\theta_I, I \in \mathcal{I}(j)\} \). Therefore, the solution \( \theta^*(j) \) always exists but it is probably non unique. To get an explicit representation for \( \theta^*(j) \) we introduce matrix notation.

First of all, we make an agreement to identify every function \( f \) with the vector \((f(X_i), i = 1, \ldots, n)\) in \( \mathbb{R}^n \) where the symbol \( \top \) means transposition. Particularly, the model function \( f \) is identified with the vector \((f(X_i), i = 1, \ldots, n)\)\( \top \).

Denote by \( N_j \) the number of elements at each level \( j \leq \log_2 n \),

\[ N_j = \#(\mathcal{I}_j) = 2^j \]

and let \( N(j) \) be the total number of elements in the set \( \mathcal{I}(j) \),

\[ N(j) = 2 + \sum_{\ell=0}^{j} N_\ell = 1 + 2^{j+1}. \] (2.7)

Introduce \( n \times N(j) \)-matrix \( \Psi(j) = (\psi_{i,I}, i = 1, \ldots, n, I \in \mathcal{I}(j)) \) with entries

\[ \psi_{i,I} = \psi_I(X_i), \quad I \in \mathcal{I}(j), \quad i = 1, \ldots, n. \] (2.8)

If \( I \neq 0,1 \), then clearly \( \psi_{i,I} = \pm 1/\sqrt{M_I} \) for \( X_i \in A_I \) and \( \psi_{i,I} = 0 \) otherwise. Here \( M_I \) is the number of design points in the interval \( A_I \) and \( \psi_{i,0} = 0 \) if \( M_I = 0 \). Also \( \psi_{i,0} = n^{-1/2} \) and \( \psi_{i,1} = X_i \left( \sum_{\ell=1}^{n} X_\ell^2 \right)^{-1/2} \). Now the approximation problem (2.6) can be rewritten in the form

\[ \theta^*(j) = \underset{\theta(j)}{\operatorname{argmin}} \| f - \Psi(j)\theta(j) \|_n^2. \]

The solution to this quadratic problem can be represented as

\[ \theta^*(j) = \left( \Psi(j)^\top \Psi(j) \right)^{-1} \Psi(j)^\top f. \] (2.9)

Strictly speaking, this representation is valid only if the matrix \( \Psi(j)^\top \Psi(j) \) is not degenerate. In the general case, one may use the similar expression for \( \theta^*(j) \) when understanding \( (\Psi(j)^\top \Psi(j))^{-1} \) as a pseudo-inverse matrix.

If the function \( f \) is linear, that is, \( f(x) = \theta_0 \psi_0(x) + \theta_1 \psi_1(x) \), we clearly get \( \theta_0^* = \theta_0 \), \( \theta_1^* = \theta_1 \) and \( \theta_I^* = 0 \) for all \( I = (\ell, k) \) with \( \ell \geq 0 \) and \( k \geq 0 \). For a non-linear function \( f \), the sum \( \sum_{\ell=0}^{j} \sum_{I \in \mathcal{I}_\ell} |\theta_I|^2 \) can be used to characterize the deviation of \( f \) from the space of linear functions.
Since the function $f$ is observed with a noise, we cannot calculate directly the coefficients $\theta_i^*$ and we consider the least squares estimator $\hat{\theta}(j)$ of the vector $\theta^*(j)$ which is defined by minimization of the sum of residuals squared:

$$
\hat{\theta}(j) = \arg\inf_{\theta(j)} \| Y - \Psi(j)\theta(j) \|^2_n = \arg\inf_{\{\theta_j \in \Omega(j)\}} \sum_{i=1}^{n} \left( Y_i - \sum_{I \in \Omega(j)} \theta_I \psi_I(X_i) \right)^2.
$$

(2.10)

Here $Y$ means the column-vector with elements $Y_i$, $i=1,\ldots,n$.

Define $V(j)$ as the pseudo-inverse of $\Psi(j)^\top \Psi(j)$, $V(j) = (\Psi(j)^\top \Psi(j))^{-}$. It is a symmetric $N(j) \times N(j)$ matrix (by $v_{I,I'}$ we denote its elements, $I,I' \in \Omega(j)$) and

$$
\hat{\theta}(j) = V(j)\Psi(j)^\top Y.
$$

(2.11)

The proposed test can be based on the squared norm $\| \hat{\theta}(j) \|^2$ of the vector $\hat{\theta}(j)$ for some $j$. This idea goes back to Neyman (1937) ‘smooth’ test. Ingster (1982, 1993) suggested the special choice of $j$ depending on the smoothness properties of the function $f$ which allows for a rate optimal testing. Spokoiny (1996) extended the method of Ingster (1993) to adaptive testing by considering all such tests for different $j$ simultaneously. Here we slightly modify that approach by considering the family of levelwise tests, that is, for every level $j$, we construct a test statistic based only on the empirical Haar coefficients $\hat{\theta}_I$ for $I \in \Omega_j$, and the resulting test is defined as the maximum of all levelwise ones.

Let some number $j(n)$ be fixed such that $2^{(n)+1} < n$ and let, for every $j \leq j(n)$, the estimate $\hat{\theta}(j)$ be defined by (2.10). Denote by $\hat{\theta}_j$ the part of the vector $\hat{\theta}(j)$ corresponding to the level $j$,

$$
\hat{\theta}_j = (\hat{\theta}_I, I \in \Omega_j).
$$

We analyze every such vector separately for all $j \leq j(n)$. Namely, for every $j \leq j(n)$, we use the statistic based on the sum $\| \hat{\theta}_j \|^2 = \sum_{I \in \Omega_j} |\hat{\theta}_I|^2$ corresponding to $j$th resolution level.

To define our test, we have to study the properties of such sums under the null hypothesis, i.e. when the function $f$ is linear: $f(x) = \theta_0 \psi_0(x) + \theta_1 \psi_1(x)$. We have already mentioned that in this situation $f = \Psi(j)\theta^*$ where $\theta_0^* = \theta_0$, $\theta_1^* = \theta_1$ and all remaining coefficients $\theta_i^*$ vanish. Therefore, using the model equation $Y = f + \xi$, we obtain

$$
\hat{\theta}(j) = V(j)\Psi(j)^\top (f + \xi)
$$

$$
= V(j)\Psi(j)^\top \Psi(j)\theta^* + V(j)\Psi(j)^\top \xi
$$

$$
= \theta^* + V(j)\Psi(j)^\top \xi.
$$

(2.12)
Obviously \( \mathbf{\zeta}(j) = V(j)\mathbf{\Psi}(j)^{\top} \mathbf{\xi} \) is a random vector in \( \mathbb{R}^{N(j)} \) with zero mean. Moreover, it holds for its covariance matrix

\[
E\mathbf{\zeta}(j)\mathbf{\zeta}(j)^{\top} = V(j)\mathbf{\Psi}(j)^{\top} E\mathbf{\xi}\mathbf{\xi}^{\top}\mathbf{\Psi}(j)V(j) = \sigma^2V(j). \tag{2.13}
\]

Due to (2.12), the subvector \( \hat{\mathbf{\theta}}_j \) of \( \hat{\mathbf{\theta}}(j) \) coincides under the null with the corresponding subvector \( \mathbf{\zeta}_j \) of the vector \( \mathbf{\zeta}(j) \), and it holds under the null in view of (2.13)

\[
E\hat{\mathbf{\theta}}_j = E\mathbf{\zeta}_j = 0,
\]

\[
E\hat{\mathbf{\theta}}_j\hat{\mathbf{\theta}}_j^{\top} = E\mathbf{\zeta}_j\mathbf{\zeta}_j^{\top} = \sigma^2V_j
\]

where \( V_j \) is the submatrix of \( V(j) \) corresponding to the index subset \( I_j : V_j = (v_{I,I'}, I, I' \in I_j) \). This particularly implies

\[
E \sum_{I \in I_j} |\hat{\theta}_I|^2 = E \sum_{I \in I_j} |\zeta_I|^2 = \sigma^2\text{tr}V_j
\]

where \( \text{tr}A \) denotes the trace of a matrix \( A \). Moreover, for the case of Gaussian errors \( \xi_i \) in (1.1), the estimates \( \hat{\theta}_I \) are also Gaussian random variables, and it holds

\[
\text{Var} \left( \sum_{I \in I_j} |\hat{\theta}_I|^2 \right) = E \left( \sum_{I \in I_j} |\hat{\theta}_I|^2 - \sigma^2\text{tr}V_j \right)^2 = E \left( \sum_{I \in I_j} |\zeta_I|^2 - \sigma^2\text{tr}V_j \right)^2 = 2\sigma^4\text{tr}V_j^2, \tag{2.14}
\]

see (2.13). This leads to the obvious idea to use the centered and standardized sum

\[
T_j = \frac{1}{\sqrt{2\sigma^4\text{tr}V_j^2}} \left( \sum_{I \in I_j} |\hat{\theta}_I|^2 - \sigma^2\text{tr}V_j \right)
\]

as a test statistic. To define our testing procedure, we simply take the maximum of all such statistics over the set of all considered Haar levels \( j \).

### 2.2 Testing procedure

First we fix the finest considered resolution level \( j(n) \) which has to satisfy \( 2^{j(n)+1} < n \) and \( n2^{-j(n)} \to \infty \), for instance,

\[
j(n) = \lfloor \log_2 n - \log_2 \log_2 n \rfloor. \tag{2.15}
\]

where \( \lfloor a \rfloor \) denotes the integer part of \( a \). For each \( j \leq j(n) \), let \( \hat{\mathbf{\theta}}(j) \) be defined by (2.11). Denote by \( \hat{\theta}_j \) the part of the vector \( \hat{\mathbf{\theta}}(j) \) corresponding to the level \( j \),

\[
\hat{\theta}_j = (\hat{\theta}_I, I \in I_j)
\]
and let $V_j$ be the submatrix of the matrix $V(j) = (\Psi(j)^\top \Psi(j))^{-}$ corresponding to the level $j$, i.e. $V_j = (u_{I,I'}, I, I' \in I_j)$. We consider $\chi^2$-type statistics

$$S_j = \|\hat{\theta}_j\|^2 = \sum_{I \in I_j} \hat{\theta}_{Ij}^2.$$ (2.16)

and define test statistics $T_j$ by centering and Studentization of $S_j$:

$$T_j = \frac{1}{\sqrt{2\hat{\sigma}^4 \text{tr} V_j^2}} \left( \sum_{I \in I_j} |\hat{\theta}_I|^2 - \hat{\sigma}^2 \text{tr} V_j \right)$$ (2.17)

where $\hat{\sigma}$ is the estimate of the error standard deviation defined in the next subsection. The proposed test rejects the null hypothesis, if at least one such statistic is significantly large, that is,

$$\phi^* = 1(T^* > \lambda) \quad \text{with} \quad T^* = \max_{j=0,\ldots,j(n)} |T_j|$$ (2.18)

where $\lambda$ is a critical value. The choice of $\lambda$ is discussed in Section 2.4.

### 2.3 Estimation of $\sigma^2$

Recall that we assume a homogeneous additive noise in the model (1.1), that is, the errors $\xi_i$ are independent identically distributed random variables fulfilling $E\xi_i = 0$ and $E\xi_i^2 = \sigma^2$. The variance $\sigma^2$ is typically unknown in practical applications but this value is important for the definition of our test procedure. Below we discuss how it can be estimated from the data $Y_1, \ldots, Y_n$. We suppose for simplicity that the design points are ordered in a way that $X_1 \leq \ldots \leq X_n$. There are several proposals for variance estimation. One possibility is to estimate $\sigma^2$ by the expression of the form

$$\hat{\sigma}^2 = \frac{1}{2(n-1)} \sum_{i=1}^{n-1} (Y_{i+1} - Y_i)^2,$$ see Rice (1984). We follow the proposal from Gasser et al. (1986) see also Hart (1997, Section 5.3) which provides an unbiased estimate of the variance under the linear null hypothesis.

Define for $i = 2, \ldots, n-1$ pseudo-residuals

$$\hat{e}_i = \frac{(X_{i+1} - X_i)}{(X_{i+1} - X_{i-1})} Y_{i-1} + \frac{(X_i - X_{i-1})}{(X_{i+1} - X_{i-1})} Y_{i+1} - Y_i = a_i Y_{i-1} + b_i Y_{i+1} - Y_i$$

which are the result of joining $Y_{i+1}$ and $Y_{i-1}$ by a straight line and taking the difference between this line and $Y_i$. A variance estimate based on these pseudo-residuals is

$$\hat{\sigma}^2 = \frac{1}{n-2} \sum_{i=2}^{n-1} \hat{e}_i^2 = \frac{1}{n-2} \sum_{i=2}^{n-1} \left( a_i^2 + b_i^2 + 1 \right).$$ (2.19)

It is easy to check that $E\hat{\sigma}^2 = \sigma^2$ if $f$ is a linear function. Some other properties of this estimates are listed in Lemmas 4.1, 4.2 and 4.9 below.
2.4 Critical value $\lambda$

Here we discuss how to select the critical value $\lambda$ to provide, at least asymptotically for large $n$, the condition $\alpha_{f_0}(\phi^*) \leq \alpha_0$ for all linear functions $f_0$. We apply a Monte-Carlo procedure by resampling from the no-response model (which is a particular case of a linear model) with standard normal errors

$$Y_{i,m}^* = \xi_{i,m}^*, \quad i = 1, \ldots, n,$$

for $m = 1, \ldots, M$, where the design points $X_1, \ldots, X_n$ are the same as for the original model (1.1), $\xi_1^*, \ldots, \xi_n^*$ are i.i.d. standard normal random variables and $M$ is the considered number of Monte-Carlo samples.

For every Monte-Carlo sample $Y_{1,m}^*, \ldots, Y_{n,m}^*$, we recalculate the test statistic $T_m^*$ from this sample using the previous procedure (including the step of variance estimation). Finally we define the critical value $\lambda$ as the $\alpha_0$-level for the set \{$T_m^*, m = 1, \ldots, M$\}:

$$\lambda = \min \left\{ t : M^{-1} \sum_{m=1}^M 1(T_m^* > t) \leq \alpha_0 \right\}.$$

This value is obviously dependent of $n$ and $M$ but it converges with growing $M$ to the proper quantile $\lambda^*$ of the $T_m^*$’s defined by

$$P(T_m^* > \lambda^*) = \alpha_0.$$

Letting $M$ go to infinity, one can make $\lambda$ arbitrary close to $\lambda^*$. To simplify our exposition, we do not distinguish between $\lambda$ and $\lambda^*$ in what follows. One can easily see that all the assertions remain valid if, for instance, $M$ fulfills $M \geq n$.

3 Main results

In this section we present the results describing asymptotic properties of the proposed testing procedure. We first discuss the properties of the test under the null and then we consider the power of the test.

3.1 Behavior under the null

Let $\phi^*$ be the test introduced above. Our first result concerns the case of Gaussian errors $\xi_i$ in the model (1.1). In this situation, independently of the design, the nominal level of the test $\phi^*$ is close to $\alpha_0$ provided that the number $M$ of Monte-Carlo samples is sufficiently large.
Theorem 3.1. Let observations $Y_i, X_i$, $i = 1, \ldots, n$, obey the regression model (1.1) with a deterministic design $X_1, \ldots, X_n$ and with i.i.d Gaussian errors $\xi_i \sim N(0, \sigma^2)$. If the function $f$ is linear, $f(x) = a + bx$, then the value $\alpha_f(\phi^*) = P_f(\phi^* = 1)$ does not depend on the coefficients $a$ and $b$ and

$$\alpha_f(\phi^*) \to \alpha_0 \quad M \to \infty.$$ 

Our next result deals with a more general situation when the errors $\xi_i$ are i.i.d. with 6 finite moments. In this case we need some mild regularity conditions on the design.

Let $M_I$ stand for the number of design points in $A_I = [2^{-j}k, 2^{-j}(k + 1)]$, that is, $M_I = \#\{i : X_i \in A_I\}$. Design regularity particularly means that each interval $A_I$ contains enough design points $X_i$.

\[ (D) \quad \text{(i) It holds for some positive constants } C_* \text{ and } C^* \text{ and all } j \leq j(n) \]
\[ \inf_{I \in \mathcal{J}_j} 2^j M_I / n \geq C_* \quad \sup_{I \in \mathcal{J}_j} 2^j M_I / n \leq C^*; \tag{3.1} \]

\[ \text{(ii) For some fixed constant } C_D \text{ and all } j \leq j(n) \]
\[ 2 \text{tr} V_j^2 \geq C_D^2 2^j \|V(j)\|_\infty^2; \]

\[ \text{(iii) For some fixed constant } C_V \text{ and all } j \leq j(n) \text{ it holds } \|V(j)\|_\infty \leq C_V; \]

\[ \text{(iv) For some } D > 0 \text{ and all } i, \text{ it holds } X_{i+1} - X_i \leq D n^{-1}. \]

In conditions (ii) and (iii), the norm $\|A\|_\infty$ of a positive symmetric matrix $A$ is understood as the maximal eigenvalue of this matrix.

It is easy to see that condition $(D)$ is fulfilled with $C_* = C^* = D = 1$, $C_D = 1 + o_n(1)$ and $C_V = 1 + o_n(1)$ for the case of the deterministic equidistant design provided that $n$ is a power of two. In this situation all the basis functions $\psi_I$ with the exception of $\psi_1$ are orthogonal to each other and, in particular, each $V_j$ is the unit matrix.

Theorem 3.2. Let observations $Y_i, X_i$, $i = 1, \ldots, n$, obey the regression model (1.1) with a deterministic design $X_1, \ldots, X_n$ satisfying $(D)$ and with i.i.d. errors $\xi_i$ satisfying $E\xi_i = 0$, $E\xi_i^2 = \sigma^2$ and $E|\xi_i^2 - \sigma^2|^3 \leq \sigma^6 C_6$ where $C_6$ is a fixed constant. If the function $f$ is linear, $f(x) = a + bx$, then

$$\alpha_f(\phi^*) = P_f(\phi^* = 1) \leq \alpha_0 + \delta_1(n),$$

where $\delta_1(n)$ depends on $n$, $C_6$ and the constants $C_*, C^*, C_D, C_V$ from condition $(D)$ only and $\delta_1(n) \to 0$ as $n \to \infty$. 
3.2 Sensitivity of the test

Now we state the results concerning the sensitivity of the proposed test $\phi^*$. The first assertion presents sufficient conditions for detecting an alternative with a high probability. Next we demonstrate how these conditions can be transferred into a more usual form about the rate of testing against a smooth alternative.

**Proposition 3.3.** Let the design $X_1, \ldots, X_n$ obey $(D)$ and the errors $\xi_1, \ldots, \xi_n$ fulfill the conditions of Theorem 3.2. Let then the regression function $f$ be two times continuously differentiable and the second derivative $f''$ fulfill the condition:

$$
\int_0^1 |f''(x)|^2 \leq L^2 \tag{3.2}
$$

with some constant $L$ satisfying $8D^3L^2 \leq \sigma^2 n^3$. Let also $\theta^*_j = (\theta^*_I, I \in J_j)$ be the subvector of the vector $\theta^*(j)$ from (2.9) corresponding to $j$ th resolution level and let $V_j$ be the corresponding covariance submatrix, $j = 1, \ldots, j(n)$. If, for some $j \leq j(n)$, it holds

$$
T^*_j \equiv \frac{\|\theta^*_j\|^2}{\sigma^2 \sqrt{2\text{tr}V_j}} \geq 3(\lambda_n^{1/2} + 1)^2, \tag{3.3}
$$

with $\lambda_n = \max\{\lambda, 2\sqrt{\log j(n)}\}$, then

$$
P(\phi^* = 0) \leq \delta(n) \to 0, \quad n \to \infty,
$$

where $\delta(n)$ depends on $n$ and the constants $C_6, C_4, C^*, C_D, C_V$ only.

We shall show, see Lemma 4.2 that, at least for sufficiently large $n$, it holds $\lambda \leq 2\sqrt{\log j(n)}(1 + o_n(1))$. Hence, the result of Proposition 3.3 means that the test $\phi^*$ detects with a probability close to one any alternative for which at least one from the corresponding values $T^*_j$ exceeds $6\sqrt{\log j(n)}(1 + o_n(1))$. Therefore, the error of the second kind may occur with a significant probability only if

$$
T^*_j \leq 6\sqrt{\log j(n)}(1 + o_n(1)), \quad 0 \leq j \leq j(n). \tag{3.4}
$$

It remains to understand what follows for the function $f$ from these inequalities.

3.3 Power against a smooth alternative

To formulate the results on the power of the test against a smooth alternative, we have to introduce some smoothness conditions on the function $f$. This can be done in different ways. We choose one based on the accuracy of approximating this function by piecewise polynomials of certain degree. Given $j \leq j(n)$, denote by $\{A_I, I \in J_j\}$ the partition of
the interval $[0, 1]$ into intervals of length $2^{-j}$: if $I = (j, k)$, then $A_I = [k2^{-j}, (k + 1)2^{-j}]$. Next, for a natural number $s$, define $\mathcal{P}_s(j)$ as the set of piecewise polynomials of degree $s - 1$ on the partition $\{A_I\}$ i.e. every function $g$ from $\mathcal{P}_s(j)$ coincides on each $A_I$ with a polynomial $a_0 + a_1 x + \ldots + a_{s-1} x^{s-1}$ where the coefficients $a_0, \ldots, a_{s-1}$ may depend on $I$. Now the condition that a function $f$ has regularity $s$ can be understood in the sense that this function is approximated by functions from $\mathcal{P}_s(j)$ with the rate $2^{-js}$, or, more precisely,

$$\inf_{g \in \mathcal{P}_s(j)} \left[ \int_0^1 (f(t) - g(t))^2 \, dt \right]^{1/2} \leq C_s 2^{-js}$$

where a positive constant $C_s$ depends on $s$ only. Taking into account the structure of the null hypothesis, for the special case with $s = 1$, corresponding to the piecewise constant (Haar) approximation, we add to the sets $\mathcal{P}_s(j)$ the linear functions, that is, $\mathcal{P}_1(j)$ is spanned by all piecewise constant functions with the pieces $A_I \in I_j$ and the linear functions.

In our conditions we change the integral by summation over observation points. This helps to present the results in a more readable form without changing the sense of required conditions. It can be easily seen that if the design is regular, then the both forms are equivalent up to a constant factor.

Let now a function $f$ be fixed. Let also $j_0$ be such that $2^{j_0 - 1} \geq s$. Define for $j \geq j_0$

$$r_s(j) = \inf_{g \in \mathcal{P}_s(j-j_0)} \|f - g\|_n = \inf_{g \in \mathcal{P}_s(j-j_0)} \left[ \sum_{i=1}^n |f(X_i) - g(X_i)|^2 \right]^{1/2}.$$  \hfill (3.5)

**Theorem 3.4.** Let condition $(D)$ hold, the errors $\xi_1, \ldots, \xi_n$ fulfill the conditions of Theorem 3.2, and the regression function $f$ obey (3.2) with a constant $L$ satisfying $8D^3 L^2 \leq \sigma^2 n^3$. There exist a constant $\kappa$ depending on the values $C_V, C_D, C_s, C^*$ and $s$ only, such that if, for some $j \leq j(n)$, the following inequality holds true:

$$\inf_{a,b} \|f - a - b \psi_1(x)\|_n \geq \kappa \left( r_s(j) + \sigma \sqrt{2^1/2 \lambda_n} \right)$$ \hfill (3.6)

with $\psi_1(x)$ proportional to $x$, then

$$P_f(\phi^* = 0) \leq \delta(n) \to 0, \quad n \to \infty,$$

where $\lambda_n$ and $\delta(n)$ are shown in Proposition 3.3.

**Remark 3.1.** It is of interest to compare this result with the existing results on the rate of hypothesis testing. For instance, it was shown in Ingster (1982, 1993) that if $f$ belongs to a Sobolev ball $W_s(1)$ with

$$W_s(1) = \left\{ f : \int_0^1 |f^{(s)}(x)|^2 \, dx \leq 1 \right\},$$

then
$f^{(s)}$ being $s$th derivative of $f$, then the optimal separation rate between the simple null $f \equiv 0$ and a smooth alternative from $W_s(1)$ is $n^{-2s/(4s+1)}$.

For our procedure, the following result is a straightforward corollary of Theorem 3.4 which for the sake of simplicity is formulated for the equidistant design only.

**Corollary 3.5.** Let the design $X_1, \ldots, X_n$ be equidistant and let $n$ be a power of two (so that condition $(D)$ holds automatically), the errors $\xi_1, \ldots, \xi_n$ fulfill the conditions of Theorem 3.2, and the underlying function $f$ belong to a Sobolev ball $W_s(1)$ and $f''$ fulfill (3.2) with a constant $L$ satisfying $8L^2 \leq \sigma^2 n^3$. Then there exists a constant $C_s > 0$ depending on $s$ only and such that, for $n$ large enough, the inequality

$$\inf_{a,b} n^{-1} \| f - a - b\psi_1 \|^2_2 \geq C_s (n/\lambda_n)^{-\frac{2s}{4s+1}}$$

implies

$$P(\phi^* = 0) \leq \delta(n) \rightarrow 0.$$

Indeed, under the equidistant design, it holds $r_s(j) \leq C n^{1/2} 2^{-js}$ for every function $f$ from $W_s(1)$ with a fixed constant $C$ depending on $s$ only. Now the right hand-side of (3.7) arises via minimization of the sum $C n^{1/2} 2^{-js} + \sqrt{2j/2 \lambda_n}$ with respect to $j$.

By comparison with the mentioned result of Ingster (1982) we observe that the proposed method leads to a near optimal separation rate up to a log-log multiple in the class of all tests. Moreover, Spokoiny (1996) has shown (for the ‘signal + white noise’ model) that this separation rate is optimal in the class of all adaptive tests. The latter result allows for a straightforward extension to Gaussian regression using the general asymptotic equivalence result, Brown and Low (1996). The additional smoothness condition (3.2) with $L^2 \leq \sigma^2 n^3 / 8$ is required for ensuring a good quality of the pilot estimate of the unknown variance. This assumption is not restrictive since the constant $L$ may rapidly grow with $n$. In particular, the low bound results from Ingster (1993) and Spokoiny (1996) allow for a straightforward extension under this constraint. Therefore the proposed test is rate optimal among all adaptive tests (at least for the case of the equidistant design).

**Remark 3.2.** The constant $\kappa$ shown in Theorem 3.4 depends on the constants $C_s$ and $C^*$ in a way that it increases when $C_s$ approaches zero or $C^*$ grows. This particularly helps to understand what happens in the case when the design is not regular and, for instance, if there exist some intervals $I$ with a small $M_I$. It was already mentioned that the procedure applies in this situation as well and the error probability of the first kind is about $\alpha_0$ at least for $n$ sufficiently large and for Gaussian errors $\xi_i$. Concerning the error probability of the second kind, design irregularity decreases the sensitivity of our
procedure in the following sense: there exist smooth alternatives with probably large $L_2$-norm which are not detected. This may occur e.g. in the situation when $f$ is deviated from the best linear approximation only in the domain with very few design points inside.

4 Proofs

In this section we first prove Theorems 3.1 and 3.4 for the case of Gaussian errors $\xi_i$ and then discuss the extension to the general case. The proofs utilize some general results on quadratic forms of Gaussian and non-Gaussian random variables which are themselves of certain interest and can be read independently of the rest. For the reference convenience, the mentioned results are collected in the Appendix.

4.1 Proof of Theorem 3.1

It suffices to check that the distribution of the test statistic $T^*$ based on the Monte-Carlo sample $Y_1^*, \ldots, Y_n^*$ is the same as for the original sample $Y_1, \ldots, Y_n$. The difference between these two samples is only in the linear trend (which can be nontrivial for the original sample but does not appear in the Monte-Carlo one) and in the noise variance (we resample with the error variance $1$ instead of $\sigma^2$). Note however that the linear trend in the regression function makes no influence on the considered test statistics $T_j$. Indeed, the numerator of this statistic is defined as the centered sum over $I_j$ of the the empirical Haar coefficients $\hat{\theta}_I$ squared, so that the linear trend is removed automatically from the test statistics, see the proof of Theorem 3.4 for more details. Similarly, the estimate $\hat{\sigma}^2$ of the noise variance $\sigma^2$ is based on the pseudo-residuals $\hat{\xi}_i$ which are defined in a way that the linear trend in the regression function is canceled out, see Lemma 4.1.

Further, for the case of zero trend, the both numerator and denominator of each $T_j$ is some quadratic forms of the errors $\xi_i$ which can be represented as $\xi_i = \sigma \tilde{\xi}_i$ with i.i.d. standard normal variables $\tilde{\xi}_i$, $i = 1, \ldots, n$. This yields, see (2.19), that the distribution of each test statistic $T_j$ does not depend on $\sigma$. The same is obviously true for the maximum $T^*$ and the assertion follows.

4.2 Properties of the estimate $\hat{\sigma}^2$

Here we discuss the properties of the estimate $\hat{\sigma}^2$ of the noise variance $\sigma^2$. We present two results. The first one describes the properties under the null, and the second one applies under a smooth alternative as well. The results are stated under the Gaussian errors $\xi_i$. For the extension, see Section 4.6.
Lemma 4.1. Let the regression function \( f \) be linear. Then \( \mathbf{E}\hat{\sigma}^2 = \sigma^2 \)
\[
\mathbf{E}(\hat{\sigma}^2 - \sigma^2)^2 \leq 7\sigma^4/(n - 2).
\]

Proof. Let \( f \) be a linear function. Then, with the coefficients \( a_i = (X_{i+1} - X_i)/(X_{i+1} - X_{i-1}) \), \( b_i = (X_i - X_{i-1})/(X_{i+1} - X_{i-1}) \), it easily holds
\[
a_i f(X_{i-1}) + b_i f(X_{i+1}) - f(X_i) = 0.
\]

Now the model equation (1.1) implies
\[
\hat{\sigma}^2 = \frac{1}{n - 2} \sum_{i=2}^{n-1} |\eta_i|^2
\]
with
\[
\eta_i = \frac{a_i \xi_{i-1} + b_i \xi_{i+1} - \xi_i}{\sqrt{a_i^2 + b_i^2 + 1}}.
\]

To estimate the difference \(|\hat{\sigma}^2 - \sigma^2|\), we apply Proposition 5.1 from the Appendix. Let \( \eta \) denote the vector \((\eta_2, \ldots, \eta_{n-1})^\top\). Obviously \( \mathbf{E}\eta = 0 \). Define \( \Sigma = \mathbf{E}\eta\eta^\top \). Observe first that
\[
\frac{1}{n - 2} \text{tr} \Sigma = \frac{1}{n - 2} \sum_{i=2}^{n-1} \mathbf{E}^2(a_i^2 + b_i^2 + 1) = \sigma^2
\]
which implies the equality \( \mathbf{E}\hat{\sigma}^2 = \sigma^2 \) by Proposition 5.1.

Next, it is easy to check that \( 2 \max\{a_i^2, b_i^2\} \leq a_i^2 + b_i^2 + 1 \). Now, it obviously holds:
\[
\mathbf{E}\eta_i^2 = \sigma^2,
\]
\[
|\mathbf{E}\eta_i\eta_{i+1}| \leq \sqrt{\mathbf{E}\eta_i^2\mathbf{E}\eta_{i+1}^2} = \sigma^2,
\]
\[
|\mathbf{E}\eta_{i-1}\eta_i| = \frac{\sigma^2 b_{i-1} a_i + 1}{\sqrt{(a_i^2 + b_{i-1}^2 + 1)(a_i^2 + b_i^2 + 1)}} \leq \sigma^2/2,
\]
\[
\mathbf{E}\eta_i\eta_{i'} = 0, \quad |i' - i| > 2,
\]

This allows to bound \( \text{tr}\Sigma^2 \) as follows:
\[
\frac{1}{(n - 2)^2} \text{tr}\Sigma^2 = \frac{1}{(n - 2)^2} \sum_{i=2}^{n-1} \sum_{j=2}^{n-1} (\mathbf{E}\eta_i\eta_j)^2
\]
\[
= \frac{1}{(n - 2)^2} \sum_{i=2}^{n-1} [(\mathbf{E}\eta_{i-1}\eta_i)^2 + (\mathbf{E}\eta_i^2)^2 + (\mathbf{E}\eta_i\eta_{i+1})^2 + (\mathbf{E}\eta_i\eta_{i-2})^2 + (\mathbf{E}\eta_i\eta_{i+2})^2]
\]
\[
\leq \frac{\sigma^4}{(n - 2)^2} \sum_{i=2}^{n-1} (1 + 1 + 1 + 1/4 + 1/4) = \frac{7\sigma^4}{2(n - 2)}
\]
which implies the second assertion of the lemma by Proposition 5.1. \( \Box \)
Next we show that \( \hat{\sigma}^2 \) estimate the true value \( \sigma^2 \) at the rate \( n^{-1/2} \) under a mild assumption on the regression function \( f \) and the design \( X_1, \ldots, X_n \). We again assume that the design points are renumbered to provide \( X_1 \leq X_2 \leq \ldots \leq X_n \).

**Lemma 4.2.** Let the design \( X_1, \ldots, X_n \) fulfill \( X_{i+1} - X_i \leq Dn^{-1} \) with some constant \( D \). Let next the regression function \( f \) from (1.1) fulfills the condition

\[
\int_0^1 |f''(x)|^2 dx \leq L^2
\]

for some \( L \geq 0 \) satisfying \( 8L^2D^3n^{-3} \leq \sigma^2 \). Then

\[
E(\hat{\sigma}^2 - \sigma^2)^2 \leq 9\alpha^4(n - 2)^{-1}.
\]

**Proof.** The definition of the coefficients \( a_i \) and \( b_i \), see Section 2.3, provides for any linear function \( \ell(x) \) the identity \( a_i \ell(X_{i-1}) + b_i \ell(X_{i+1}) - \ell(X_i) = 0 \). The application of \( \ell(x) = f'(x)(x-X_i) \) yields

\[
|a_if(X_{i-1}) + b_if(X_{i+1}) - f(X_i)| \\
\leq a_i|f(X_{i-1}) - f(X_i) - f'(X_i)(X_{i-1} - X_i)| + b_i|f(X_{i+1}) - f(X_i) - f'(X_i)(X_{i+1} - X_i)|.
\]

Let \( f(X_{i-1}) - f(X_i) = (X_{i-1} - X_i)f'(u) \) for some \( u \in [X_{i-1}, X_i] \). Then, by the Cauchy-Schwarz inequality and the condition \( X_i - X_{i-1} \leq Dn^{-1} \),

\[
|f(X_{i-1}) - f(X_i) - f'(X_i)(X_{i-1} - X_i)| \leq (X_i - X_{i-1}) \left| \int_{X_{i-1}}^{X_i} f''(s) ds \right|
\leq (X_i - X_{i-1}) \int_{X_{i-1}}^{X_i} |f''(x)| dx \leq (X_i - X_{i-1})^{3/2} \left( \int_{X_{i-1}}^{X_i} |f''(x)|^2 dx \right)^{1/2} \leq (Dn^{-1})^{3/2} L_i
\]

with \( L_i^2 = \int_{X_{i-1}}^{X_i} |f''(x)|^2 dx \), and similarly for \( |f(X_{i+1}) - f(X_i) - f'(X_i)(X_{i+1} - X_i)| \).

These two bounds imply

\[
|a_if(X_{i-1}) + b_if(X_{i+1}) - f(X_i)| \leq (a_iL_i + b_iL_{i+1}) (Dn^{-1})^{3/2}. \tag{4.1}
\]

Next, define

\[
\eta_i = \frac{a_i \xi_{i-1} + b_i \xi_{i+1} - \xi_i}{\sqrt{a_i^2 + b_i^2 + 1}}, \quad \Delta_i = \frac{a_i f(X_{i-1}) + b_i f(X_{i+1}) - f(X_i)}{\sqrt{a_i^2 + b_i^2 + 1}}.
\]

Then

\[
\hat{\sigma}^2 = \frac{1}{n - 2} \sum_{i=2}^{n-1} |\Delta_i + \eta_i|^2.
\]

To estimate the difference \( \hat{\sigma}^2 - \sigma^2 \), we apply Proposition 5.2 from the Appendix. Let \( \eta = (\eta_2, \ldots, \eta_{n-1})^T \). We know, see the proof of Lemma 4.1, that \( E\eta = 0 \) and the matrix \( \Sigma = E\eta\eta^T \) fulfills
The inequality $2 \max \{a_i^2, b_i^2 \} \leq 1 + a_i^2 + b_i^2$ and (4.1) provide

$$
\|\Delta\|^2 = \sum_{i=2}^{n-1} \Delta_i^2 \leq D^3 n^{-3} \sum_{i=2}^{n-1} \frac{(a_i L_i + b_i L_{i+1})^2}{a_i^2 + b_i^2 + 1}
$$

$$
\leq D^3 n^{-3} \sum_{i=2}^{n-1} (L_i^2 + L_{i+1}^2) \leq 2D^3 n^{-3} \int_0^1 |f''(x)|^2 dx \leq 2D^3 n^{-3} L^2
$$

The application of Proposition 5.2 from the Appendix with $c = \Delta/(n - 2)^{1/2}$ and $\varepsilon = \eta/(n - 2)^{1/2}$ yields

$$
E (\hat{\sigma}^2 - \sigma^2)^2 = E (\|c + \varepsilon\|^2 - \operatorname{tr}V)^2 \leq \|c\|^4 + 4\|c\|^2 (\sqrt{\operatorname{tr}V^2} + 2\operatorname{tr}V^2).
$$

where $V = (n - 2)^{-1} \Sigma$. This along with the inequalities $\operatorname{tr}V^2 \leq 7/2 \sigma^4/(n - 2)$ and $4\|c\|^2 \leq 8L^2 D^3 n^{-3} (n - 2)^{-1} \leq \sigma^2 (n - 2)^{-1}$ imply the required assertion.

4.3 Critical value $\lambda$

Here we present an upper bound for the critical value $\lambda$ defined in Section 2.4.

**Lemma 4.3.** Let $N_j = 2^j$ denote the number of elements in the set $I_j$. It holds

$$
\operatorname{tr}V_j \leq \sqrt{2\operatorname{tr}V_j^2} \sqrt{N_j}/2.
$$

**Proof.** Clearly

$$
\operatorname{tr}V_j^2 = \sum_{l \in \beta_j} \sum_{l' \in \beta_j} v_{l,l'}^2 \geq \sum_{l \in \beta_j} v_{l,l}^2.
$$

Next, the Cauchy-Schwarz inequality implies

$$
N_j^{-1} \operatorname{tr}V_j = N_j^{-1} \sum_{l \in \beta_j} v_{l,l} \leq \left( N_j^{-1} \sum_{l \in \beta_j} v_{l,l}^2 \right)^{1/2}
$$

and the assertion follows.

**Lemma 4.4.** Let $\lambda$ be the critical value of the test selected by the testing procedure. If design $X_1, \ldots, X_n$ fulfills (D), then, for $n$ sufficiently large,

$$
\lambda \leq 2\sqrt{\log j(n)} (1 + o_n(1)).
$$
Proof. Recall that the critical value $\lambda$ corresponds to the $1-\alpha_0$-quantile of the distribution of the test statistic $T^* = \max_{j \leq j(n)} T_j$ under the no-response model $f(x) \equiv 0$ and under the assumption of standard normal errors $\xi_i, \ i = 1, \ldots, n$. In such a situation, the subvector $\hat{\theta}_j$ of $\hat{\theta}(j)$ coincides with the Gaussian vector $\zeta_j \sim N(0, V_j)$, see Section 2.1, and hence the corresponding statistic $T_j$ can be represented in the form

$$T_j = \frac{\|\zeta_j\|^2 - \sigma^2 \text{tr} V_j}{\hat{\sigma}^2 \sqrt{2\text{tr} V_j^2}}.$$  

and it suffices to show that

$$P \left( \max_{j \leq j(n)} T_j > 2\sqrt{\log j(n)}(1 + \delta_1(n)) \right) \leq \delta_2(n)$$

with two numeric sequences $\delta_1(n) \to 0$ and $\delta_2(n) \to 0$.

Now, for every $z \geq 1$ and $a \in (0, 1)$,

$$\left\{ T_j > \frac{z + 1}{a} \right\} = \left\{ \frac{\|\zeta_j\|^2 - \hat{\sigma}^2 \text{tr} V_j}{\sigma^2 \sqrt{2\text{tr} V_j^2}} > \frac{(z + 1)\hat{\sigma}^2}{a\sigma^2} \right\} \subseteq \left\{ \frac{\|\zeta_j\|^2 - \sigma^2 \text{tr} V_j}{\sigma^2 \sqrt{2\text{tr} V_j^2}} > z \right\} \cup \left\{ \frac{(\sigma^2 - \hat{\sigma}^2)\text{tr} V_j}{\sigma^2 \sqrt{2\text{tr} V_j^2}} > 1 \right\} \cup \left\{ \frac{\hat{\sigma}^2}{\sigma^2} < a \right\}.$$  

This clearly yields in view of Lemma 4.3

$$P \left( \max_{j \leq j(n)} T_j > \frac{z + 1}{a} \right) \leq P \left( \frac{\hat{\sigma}^2}{\sigma^2} < a \right) + P \left( \frac{\hat{\sigma}^2}{\sigma^2} - 1 < -\frac{1}{N_j(n)/2} \right) + \sum_{j=0}^{j(n)} P \left( \frac{\|\zeta_j\|^2 - \sigma^2 \text{tr} V_j}{\sigma^2 \sqrt{2\text{tr} V_j^2}} > z \right).$$

We apply this bound with $z = 1 + v_n$ and $a = 1 - v_n^{-1}$ where $v_n = 2\sqrt{\log j(n)}$. By (D.iii), in view of $\|V_j\| \leq \|V(j)\|_\infty$, it holds $\sqrt{2\text{tr} V_j^2} \geq C D 2j/2 \|V_j\|_\infty$. Now an application of Proposition 5.1 from the Appendix with $\gamma = v_n$ allows to bound

$$P \left( \frac{\|\zeta_j\|^2 - \sigma^2 \text{tr} V_j}{\sigma^2 \sqrt{2\text{tr} V_j^2}} > v_n + 1 \right) \leq e^{-(v_n+1)^2/4} + e^{-v_n \sqrt{2\text{tr} V_j^2}/(6\|V_j\|_\infty)} \leq e^{-(v_n+1)^2/4} + e^{-v_n C D 2j/2 / 6}.$$  

Lemma 4.1 and the Chebyshev inequality provide

$$P \left( \frac{\hat{\sigma}^2}{\sigma^2} < 1 - v_n^{-1} \right) + P \left( \frac{\hat{\sigma}^2}{\sigma^2} - 1 > \frac{1}{\sqrt{N_j(n)/2}} \right) \leq v_n^{-4} E (\hat{\sigma}^2 - \sigma^2)^2 + \frac{N_j(n) E (\hat{\sigma}^2 - \sigma^2)^2}{2\sigma^4} \leq \frac{7v_n^2}{2(n-2)} + \frac{7N_j(n)}{4(n-2)} = \delta_3(n) \to 0,$$
since, by definition of \( j(n) \), it holds \( n/N_j(n) \to \infty \). Therefore, with some fixed constant \( C \),

\[
P \left( T_n > \frac{2 + v_n}{1 - v_n} \right) \leq \delta_3(n) + \sum_{j=0}^{j(n)} e^{-v_n^2/4 - v_n/2} + \sum_{j=0}^{j(n)} e^{-v_n C \theta^2 j^2 / 6} \\
\leq \delta_3(n) + \frac{1 + (j(n)/n)}{\log n} e^{-v_n/2} + C e^{-v_n C \theta^2 j^2 / 6} \to 0, \quad n \to \infty.
\]

\[
\square
\]

4.4 Proof of Proposition 3.3 for Gaussian errors \( \xi_i \)

Recall that the vector \( \hat{\theta}_j \) is defined as the subvector of \( \hat{\theta}(j) = (\Psi(j)^\top \Psi(j))^{-1} \Psi(j)^\top Y \), \( j \leq j(n) \). The model equation (1.1) yields

\[
\hat{\theta}(j) = (\Psi(j)^\top \Psi(j))^{-1} \Psi(j)^\top (f + \xi) = \theta^\ast(j) + \zeta(j)
\]

with \( \theta^\ast(j) = V_j \Psi(j)^\top f \) and \( \zeta(j) = V_j \Psi(j)^\top \xi \) where \( V(j) = (\Psi(j)^\top \Psi(j))^{-1} \).

Hence \( \hat{\theta}_j = \theta^\ast_j + \zeta_j \) where \( \theta^\ast_j \) (resp. \( \zeta_j \)) is the subvector of \( \theta^\ast(j) \) (resp. of \( \zeta(j) \)) corresponding to the \( j \)th resolution level. This particularly implies that \( \zeta_j \) is a zero mean random vector with the covariance matrix \( \sigma^2 V_j \) where \( V_j \) is the submatrix of the matrix \( V(j) = (\Psi(j)^\top \Psi(j))^{-1} \). Moreover, if the errors \( \xi_i \) in (1.1) are Gaussian, then \( \zeta_j \) is a Gaussian random vector with parameters \((0, \sigma^2 V_j)\) for each \( j \leq j(n) \).

Let, for some \( j \leq j(n) \), it holds

\[
T^*_j = \frac{\|\theta^\ast_j\|^2}{\sigma^2 \sqrt{2 \text{tr} V_j^2}} \geq 3(\lambda_n^{1/2} + 1)^2
\]

with \( \lambda_n = \max\{\lambda, 2\sqrt{\log j(n)}\} \). We shall show that under this condition

\[
P_f(T_j < \lambda) \leq \delta(n) \to 0, \quad n \to \infty,
\]

which obviously implies the assertion.

Define \( S_j = \sqrt{2 \text{tr} V_j^2} \). Observe first that in view of \( \lambda \leq \lambda_n \)

\[
P (T_j < \lambda) \leq P (\|\theta^\ast_j + \zeta_j\|^2 - \sigma^2 \text{tr} V_j < \lambda_n \sigma^2 S_j) \\
\leq P (\|\theta^\ast_j + \zeta_j\|^2 - \sigma^2 \text{tr} V_j < \lambda_n \sigma^2 S_j + (\sigma^2 - \sigma^2) (\lambda_n S_j + \text{tr} V_j)) \\
\leq P (\|\theta^\ast_j + \zeta_j\|^2 - \sigma^2 \text{tr} V_j - \|\theta^\ast_j\|^2 < (\lambda_n + \lambda_n^{1/2}) \sigma^2 S_j - \|\theta^\ast_j\|^2) \\
+ P (\sigma^2 - \sigma^2) (\lambda_n S_j + \text{tr} V_j) > \sigma^2 \lambda_n^{1/2} S_j).
\]

By Lemma 4.3 \( \text{tr} V_j/S_j \leq \sqrt{N_j/2} \leq \sqrt{N_j(n)/2} \) for all \( j \leq j(n) \). Further, by Lemma 4.2

\[
P \left( \|\zeta_j\|^2 \leq \frac{\lambda_n S_j + \text{tr} V_j}{\lambda_n S_j + \text{tr} V_j} \right) \leq \frac{(\lambda_n S_j + \text{tr} V_j)^2}{\sigma^4 \lambda_n S_j^2} E (\sigma^2 - \sigma^2)^2 \leq \frac{9(\lambda_n + \sqrt{N_j(n)/2})^2}{\lambda_n (n - 2)} = \delta_4(n), \quad n \to \infty
\]
since \( n/N_j(n) = n2^{-j(n)} \to \infty \).

Next, for every positive \( u \), the inequality \( \|\theta\| \geq 3u \) implies \( \|\theta\|^2 - 2u\|\theta\| - 3u^2 \geq 0 \). Coupled with (4.2), this ensures with \( u = 3^{-1/2}(\lambda_n^{1/2} + 1)\sigma S_j^{1/2} \) that

\[
\|\theta_j^*\|^2 \geq \sqrt{\frac{4}{3}}\|\theta_j^*\|((\lambda_n^{1/2} + 1)\sigma S_j^{1/2} + (\lambda_n^{1/2} + 1)^2\sigma^2 S_j)
\geq \|\theta_j^*\|((\lambda_n^{1/2} + 1)\sigma S_j^{1/2} + (\lambda_n + 2\lambda_n^{1/2} + 1)\sigma^2 S_j).
\]

Now, the use of Proposition 5.2 from the Appendix with \( \gamma = \lambda_n^{1/2} + 1 \) and \( c = \theta_j \) and of (D.iii) yields

\[
P(T_j < \lambda) \leq P \left( \|\theta_j^* + \zeta_j\|^2 - \sigma^2 \text{tr}V_j - \|\theta_j^*\|^2 < -(\lambda_n^{1/2} + 1)\|\theta_j^*\|\sigma S_j^{1/2} - (\lambda_n^{1/2} + 1)\sigma^2 S_j \right) + \delta_4(n)
\leq 2e^{-\lambda_n/4 + e^{-\lambda_n^{1/2}2^j\sigma^2 S_j/6}\|V_j\|\infty} + \delta_4(n)
\leq 2e^{-\lambda_n/4 + e^{-\lambda_n^{1/2}2^j\sigma^2 S_j/6} + \delta_4(n) \to 0, \quad n \to \infty,}
\]
as required.

### 4.5 Proof of Theorem 3.4 for Gaussian errors

For the proof, we use the result of Proposition 3.3. Namely we show that the condition (3.6) of the theorem with \( \kappa \) large enough contradict to the constraint

\[
T_j^* \leq t_n, \quad j \leq j(n), \tag{4.4}
\]

with \( t_n = 3 \left( 1 + \lambda_n^{1/2} \right)^2 \) and \( \lambda_n = \max \{ \lambda, 2\sqrt{\log j(n)} \} \).

We begin by reduction of the problem of testing a linear hypothesis to the problem with a simple null hypothesis. Define coefficients \( \theta_0, \theta_1 \) by

\[
(\theta_0, \theta_1) = \arg\inf\limits_{(a,b)} \|f - a - b\psi_1\|_n
\]

and set

\[
f_0 = f - \theta_0 - \theta_1\psi_1.
\]

Note that for all \( j \geq 0 \), the vectors \( \theta^*(j) = V(j)\Psi(j)^\top f \) and \( \theta(j) = V(j)\Psi(j)^\top f_0 \) have the same components except the first two. Obviously the smoothness properties of \( f \) and \( f_0 \) also coincide and

\[
\inf\limits_{a,b} \|f - a - b\psi_1\|_n = \inf\limits_{a,b} \|f_0 - a - b\psi_1\|_n
\]

Recall also, that the linear trend in the regression function has no influence on our variance estimator \( \hat{\sigma}^2 \). Hence, replacing \( f \) by \( f_0 \) changes nothing in the test behaviour.
and we may suppose from the beginning that the projection of $f$ on the space of the
linear functions vanish.

About this new function $f$ we know that

$$\|f\|_n = \inf_{a,b} \|f - a - b\psi_1\|_n \geq \kappa \left( r_s(j) + \sigma \sqrt{2j/\lambda_n} \right),$$

$$\inf_{g \in \mathcal{P}_s(j-j_0)} \|f - g\|_n = r_s(j),$$

(4.5)

for some $0 \leq j \leq j(n)$.

Next we rewrite the constraints from (4.4) in term of the vectors $\|\theta^*_j\|$, $j \leq j(n)$. Recall that $\theta^*_j$ is the subvector of $\theta^*(j)$ corresponding to $j$th level, and $V_j$ is the corresponding submatrix of $V(j)$.

Let $\mathcal{L}(j)$ stand for the linear space generated by functions $\psi_I$, $I \in \mathcal{I}(j)$. We denote also by $\Pi(j)f$ the projection of $f$ onto the space $\mathcal{L}(j)$ with respect to the norm $\|\cdot\|_n$, $\Pi(j)f = \arg\inf_{h \in \mathcal{L}(j)} \|f - h\|_n.$

Particularly, $\Pi(0)f$ denotes the projection of $f$ onto the space of linear functions (and hence, $\Pi(0)f = 0$) and, by definition of $\theta^*(j)$,

$$\Pi(j)f = \sum_{I \in \mathcal{I}(j)} \theta^*_I \psi_I$$

(4.6)

where the $\theta^*_I$’s denote the coefficients of the vector $\theta^*(j)$.

**Lemma 4.5.** For each $1 \leq j \leq j(n)$,

$$\|\Pi(j)f\|_n \leq \|\Pi(j-1)f\|_n + \|\theta^*_j\|.$$  

*Proof.* Since $\mathcal{L}(j-1) \subseteq \mathcal{L}(j)$, then

$$\Pi(j-1)f = \Pi(j-1)\Pi(j)f.$$  

When denoting $f(j) = \Pi(j)f$, one has $\Pi(j-1)f = \Pi(j-1)f(j)$ and we have to show that

$$\|\Pi(j-1)f(j)\|_n \geq \|f(j)\|_n - \|\theta^*_j\|.$$  

In view of (4.6)

$$f(j) = \sum_{I \in \mathcal{I}(j)} \theta^*_I \psi_I.$$  

Denote by $f_j$ the part of this sum corresponding to the last level $j$ in $\mathcal{I}(j)$,

$$f_j = \sum_{I \in \mathcal{I}_j} \theta^*_I \psi_I.$$
By construction, the functions $\psi_I, I \in J_j$, are orthonormal w.r.t. to the Euclidean norm $\| \cdot \|_n$ and particularly
\[
\| f_j \|_n^2 = \sum_{I \in J_j} |\theta_I^*|^2 = \| \theta_j^* \|^2.
\]
Next, obviously $f(j) - f_j \in L(j-1)$, and by definition of $\Pi(j)$,
\[
\| f(j) - \Pi(j-1)f(j) \|_n \leq \| f(j) - (f(j) - f_j) \|_n = \| f_j \|_n = \| \theta_j^* \|
\]
and the assertion follows by the triangle inequality.

Lemma 4.6. Given $j \leq j(n)$, let (4.4) hold true for all $\ell \leq j$. Then
\[
\| \Pi(j)f \|_n^2 \leq \kappa_1 \sigma^2 C_V 2^{j/2} t_n
\]
with $\kappa_1 = 2^{1/2}(2^{1/4} - 1)^{-2}$.

Proof. Recursive application of Lemma 4.5 gives
\[
\| \Pi(j)f \|_n \leq \| \theta_1^* \| + \ldots + \| \theta_{j-1}^* \|.
\]
Here we have used that $\Pi(0)f = 0$. Now (4.4) and (D.iii) yield in view of $\text{tr} V_\ell^2 \leq 2^\ell \| V_\ell \|^2 \leq 2^\ell \| V(\ell) \|^2$
\[
\| \theta_j^* \|^2 \leq \sigma^2 t_n \sqrt{2 \text{tr} V_\ell^2} \leq \sigma^2 t_n \sqrt{C_V^2 2^{\ell+1}}
\]
and thus,
\[
\| \Pi(j)f \|_n \leq \sum_{\ell=1}^j \sigma \left( 2^{\ell/2} t_n C_V \right)^{1/2} = \sigma (C_V t_n)^{1/2} \sum_{\ell=1}^j 2^{\ell/4}
\]
and the assertion follows by simple algebra.

Let now $j_0$ fulfill $2^{j_0} > s$ and $P_s(j - j_0)$ denote the space of piecewise polynomials with piece length $2^{-(j - j_0)}$. Let now some $j \leq j(n)$ be fixed and let $g \in P_s(j - j_0)$ be such that
\[
\| f - g \|_n = r_s(j).
\]

Lemma 4.7. There is a constant $\kappa_2 > 0$ depending on $C_s, C^*$ and $s$ only and such that for each $j$ with $j_0 \leq j \leq j(n)$
\[
\| f \|_n \leq \kappa_2 \{ \| \Pi(j)f \|_n + r_s(j) \}.
\]
Proof. Let \( g \in P_s(j - j_0) \) be such that \( \| f - g \|_n \leq r_s(j) \). Then
\[
\| f \|_n \leq \| g \|_n + r_s(j)
\]
and, since \( \Pi(j) \) is a projector,
\[
\| \Pi(j)f \|_n = \| \Pi(j)g + \Pi(j)(f - g) \|_n \geq \| \Pi(j)g \|_n - \| \Pi(j)(f - g) \|_n \geq \| \Pi(j)g \|_n - r_s(j)
\]
and the assertion follows from
\[
\| g \|_n^2 \leq \kappa_3 \| \Pi(j)g \|_n^2.
\]
Recall that \( g \) is a piecewise polynomial function on the partition \( A_I, I \in \mathcal{I}_j-j_0 \) and \( \Pi(j)g \) projects \( g \) (that is a polynomial within each interval \( A_I \) of length \( 2^{-j-j_0} \)) on the space containing all the piecewise constant functions with piece length \( 2^{-j} \). Therefore, it suffices to prove that for each piece \( A_I \) and every polynomial \( P(x) = a_0 + a_1 x + \ldots + a_{s-1}x^{s-1} \), it holds
\[
\sum_{A_I} P_j^2(X_i) \geq \kappa_3 \sum_{A_I} P^2(X_i)
\]
where \( P_j \) is the projection of \( P \) on the space of piecewise constant functions on \( A_I \) with the piece length \( 2^{-j} \) and the constant \( \kappa_3 \) depends on \( C_s, C^* \) and \( s \) only. The similar fact with integration instead of summation over the design points in \( A_I \) has been stated in Ingster (1993) and we present here only a sketch of the proof for our situation.

The key idea of the proof can be formulated as a separate statement.

**Lemma 4.8.** Let \( P(x) \) be a polynomial of degree \( s - 1 \) and let \( m \) be an integer with \( m > s \). Define \( A_k = [(k - 1)/m, k/m] \) for \( k = 1, \ldots, m \). Then for every measure \( \mu \) on \([0, 1]\) with \( 0 < C_s \leq \mu(A_k) \leq C^* > 0 \) for all \( k \leq m \),
\[
\sum_{k=1}^m \left[ \int_{A_k} P(x) \mu(dx) \right]^2 \geq \kappa_3 \int_0^1 P^2(x) \mu(dx).
\]
with a positive number \( \kappa_3 \) depending on \( C_s, C^* \) and \( s \) only.

**Proof.** Let \( a = (a_0, \ldots, a_{s-1}) \) be the vector of coefficients of \( P \). Without loss of generality, we may assume that \( \| a \|_{\infty} = \max_{j=0,\ldots,s-1} \{|a_j|\} = 1 \). Otherwise normalize \( P \) by \( \| a \|_{\infty} \). Obviously, the both \( \| a \|_{\mu, 1} \) and \( \| a \|_{\mu, 2} \) defined by
\[
\| a \|_{\mu, 1}^2 = \sum_{k=1}^m \left( \int_{A_k} P(x) \mu(dx) \right)^2,
\]
\[
\| a \|_{\mu, 2}^2 = \int_0^1 P^2(x) \mu(dx),
\]
are some Euclidean norms in the space $\mathbb{R}^s$. Next, $\|a\|_{\mu,2} = 0$ is impossible under $\|a\|_\infty = 1$ and the same applies for $\|a\|_{\mu,1}$, since $P(x)$ has at most $s - 1$ roots and $\mu$ is supported on $m > s$ disjoint intervals. Note also that $\|a\|_{\mu,1}$ and $\|a\|_{\mu,2}$ are continuous functionals of $a$ and $\mu$ and the space $\mathcal{M}_m(C_*, C^*)$ of measures $\mu$ on $[0, 1]$ satisfying the condition of the lemma is compact in the weak topology. Hence,

$$\sup_{a : \|a\|_\infty = 1} \sup_{\mu \in \mathcal{M}_m(C_*, C^*)} \frac{\|a\|_{\mu,2}}{\|a\|_{\mu,1}} = \kappa_3 < \infty$$

as required.

Application of this result to each interval $A_{I_j}, I \subseteq \mathbb{I}_{j-\delta_0}$ yields the desirable assertion.

The results of Lemmas 4.6 through 4.7 yield the inequality

$$\|f\|_n \leq \kappa_2 \left( r_s(j) + \sigma \sqrt{\kappa_1 C V 2^{j/2} \lambda_n} \right)$$

which contradicts to the constraints $\|f\|_n \geq \kappa \left( r_s(j) + \sigma \sqrt{2^{j/2} \lambda_n} \right)$ with a sufficiently large $\kappa$, and the theorem is proved.

### 4.6 Proof of Theorem 3.2

Now we disregard the assumption that the errors $\xi_i$ in (1.1) are normally distributed and assume only that they have 6 finite moments. We outline the proof of Theorem 3.2 only. Proposition 3.3 can be considered similarly. The result of Theorem 3.4 for the non-Gaussian errors follows from Proposition 3.3.

**Lemma 4.9.** Let the errors $\xi_i$ in (1.1) be i.i.d. and satisfy $E \xi_i = 0, \xi_i^2 = \sigma^2$ and $E |\xi_i^2 - \sigma^2|^3 \leq C_6 \sigma^6$. Define $s_4^2 = 2 \sigma^{-4} \max_{i=1,...,n} E (\xi_i^2 - \sigma^2)^2$. If the regression function $f$ is linear then

$$E (\hat{\sigma}^2 - \sigma^2)^2 \leq (s_4 + 1/2) \sigma^4/(n - 2).$$

**Proof.** Similarly to the Gaussian case discussed in Section 4.2, it suffices to consider the case of the no-response model with the vanishing regression function. In this case, the variance estimate $\hat{\sigma}^2$ is a quadratic form of the errors $\xi_i$ which can be represented as follows:

$$\hat{\sigma}^2 = \frac{1}{n - 2} \sum_{i=2}^{n-1} \frac{(a_i \xi_{i-1} + b_i \xi_{i+1} - \xi_i)^2}{a_i^2 + b_i^2 + 1}$$
where \( a_i = (X_i + 1 - X_i)/(X_i + 1 - X_{i-1}) \), \( b_i = (X_i - X_{i-1})/(X_i + 1 - X_{i-1}) \), \( i = 1, \ldots, n \).

Simple algebra yields

\[
(n - 2)(\hat{\sigma}^2 - \sigma^2) = \sum_{i=1}^{n} a_i^2 (\xi_{i-1}^2 - \sigma^2) + b_i^2 (\xi_{i+1}^2 - a^2) + (\xi_i^2 - a^2) + 2 \sum_{i=2}^{n-1} a_i b_i \xi_{i-1} \xi_{i+1} - a_i \xi_{i-1} \xi_i - b_i \xi_i \xi_{i+1}
\]

\[
\sum_{i=2}^{n-1} \left( \frac{a_i^2}{a_i^2 + b_i^2 + 1} + \frac{1}{a_i^2 + b_i^2 + 1} + \frac{b_i^2}{a_i^2 + b_i^2 + 1} \right) (\xi_i^2 - \sigma^2)
\]

\[
+ 2 \sum_{i=2}^{n-1} \frac{a_i b_i}{a_i^2 + b_i^2 + 1} \xi_{i-1} \xi_{i+1} - 2 \sum_{i=2}^{n-1} \left( \frac{a_i}{a_i^2 + b_i^2 + 1} + \frac{b_i}{a_i^2 + b_i^2 + 1} \right) \xi_{i-1} \xi_i
\]

\[
= \sum_{i=1}^{n} \alpha_{ii} (\xi_i^2 - \sigma^2) + \sum_{i \neq j} \alpha_{ij} \xi_i \xi_j
\]

where \( a_j = b_j = 0 \) for \( j = 0, 1, n, n + 1 \) and \( \alpha_{ij} \) are some coefficients. This clearly implies \( E\hat{\sigma}^2 = \sigma^2 \). It is also easy to see that

\[
(n - 2)^2 E(\hat{\sigma}^2 - \sigma^2)^2 = \sigma^4 \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_{ij}^2 + \sigma^4 (s_4 - 3) \sum_{i=1}^{n} \alpha_{ii}^2
\]

where \( s_4 = \sigma^{-4} E(\xi_i^2 - \sigma^2)^2 \). One can easily check that the matrix \( A \) with the entries \( \alpha_{ij} \) fulfills

\[
\sigma^4 \text{tr} A^T A = \sigma^4 \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_{ij}^2 = \text{tr} \Sigma^2
\]

with the matrix \( \Sigma \) defined in Lemma 4.1 and hence, \( \sigma^4 \text{tr} A^T A \leq (7/2) \sigma^4 (n - 2) \). Since \( \sum_{i=1}^{n} \alpha_{ii} = n - 2 \) and \( \alpha_{ii} \leq 2 \) for all \( i \), we derive

\[
\frac{1}{n - 2} \sum_{i=1}^{n} \alpha_{ii}^2 \leq \frac{\max_{1 \leq i \leq n} \alpha_{ii}}{n - 2} \sum_{i=1}^{n} \alpha_{ii} \leq 2
\]

and

\[
E(\hat{\sigma}^2 - \sigma^2)^2 \leq \frac{7 \sigma^4}{2(n - 2)} + (s_4 - 3) \sigma^4 \frac{2}{n - 2} \leq \frac{(s_4 + 1/2) \sigma^4}{n - 2}.
\]

\[\square\]

In the same way one can extend the result of Lemma 4.2 to the non-Gaussian case: \( \hat{\sigma}^2 \) estimates the true variance \( \sigma^2 \) at the rate \( n^{-1/2} \) provided that \( f \) is sufficiently smooth.

Now we turn to Theorem 3.2. It obviously suffices to show that the distribution of the test statistic \( T^* \) can be approximated by a similar distribution corresponding to the case of Gaussian errors. Then the result follows from Theorem 3.1.
As in the proof of Theorem 3.1, the general case can be reduced to the no-response model with the vanishing regression function. Further, since the difference $\tilde{\sigma}^2 - \sigma^2$ is of order $n^{-1/2}$, it suffices to consider the expressions $T'_j$, $j \leq j(n)$, defined by

$$T'_j = \frac{1}{\sqrt{2\sigma^4 tr V_j^2}} \left( \sum_{i \in J_j} |\tilde{\theta}_i|^2 - \sigma^2 tr V_j \right) = \frac{S_j - \sigma^2 tr V_j}{\sqrt{2\sigma^4 tr V_j^2}}$$

where $\tilde{\theta}_i$ are elements of the vector $\tilde{\Theta}(j)$, cf. the proof of Lemma 4.4. Under the no-response hypothesis, this vector admits the representation: $\tilde{\Theta}(j) = W(j)\xi$ with $W(j) = (\Psi(j)^{\top}\Psi(j))^{-1}\Psi(j)^{\top}$, see (2.12). If $E_j$ denotes the projector from $J(j)$ onto $J_j$ keeping the coordinates $x_i$ with $i \in J_j$, then $\tilde{\theta}_j = E_j\tilde{\Theta}(j) = E_jW(j)\xi$ and

$$S_j = \|\tilde{\Theta}_j\|^2 = \xi^T W(j)^{\top} E_j^T E_j W(j)\xi = \xi^T A_j \xi$$

with $A_j = W(j)^{\top} E_j^T E_j W(j)$, so that $S_j$ is a quadratic form of the errors $\xi_i$. We also know that $V_j = E_j W(j)^{\top} E_j^T$, and $ES_j = \sigma^2 tr A_j = \sigma^2 tr V_j$. The form $A_j$ in its turn can be represented as a sum of a diagonal form $T_j^{(1)}$ and a quadratic form $T_j^{(2)}$ with vanishing diagonal terms. We first show that the contribution of diagonal terms is negligible and then apply Corollary 5.8 to the $T_j^{(2)}$'s.

Let $o_i$ denote the $i$-th basis vector in $\mathbb{R}^n$. Then the $i$-th diagonal element $a_{ii}$ of $A_j$ is equal to $o_i^T A_j o_i$:

$$a_{ii} = o_i^T A_j o_i = o_i^T \Psi(j) \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} E_j^T E_j \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} \Psi(j)^{\top} o_i.$$ 

Clearly

$$\left\| \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} E_j^T E_j \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} \right\|_\infty \leq \left\| \left( \Psi(j)^{\top} \Psi(j) \right)^{-2} \right\|_\infty = \|V_j\|_\infty^2.$$ 

Next, for every Haar level $\ell \leq j$, there exists only one index $i \in I_\ell$ such that $\psi(I(X_i)) \neq 0$. More precisely, for this index $i$, it holds $\psi(I(X_i)) = \pm 1/\sqrt{M_I}$ where $M_I$ is the number of design points in the interval $A_I$ corresponding to the index $I$. Condition (D.i) implies $M_I \geq C_n 2^{-\ell}$ for every $I \in I_\ell$. Also $\psi_0(X_i) = n^{-1/2}$ and $\psi_1(X_i) = X_i \left( \sum_{i=1}^n X_{i}^2 \right)^{-1/2}$. Hence, the definition of the matrix $\Psi(j)$ and condition (D.i) provide

$$|\Psi(j)^{\top} o_i| \leq n^{-1/2} + \left( \sum_{i'=1}^n X_{i'}^2 \right)^{-1/2} + \sum_{\ell=0}^j \sqrt{\frac{2\ell}{nC_s}} < 3C_s^{-1/2} 2^{j/2} n^{-1/2}. \text{ (4.8)}$$

Therefore,

$$a_{ii} \leq |\Psi(j)^{\top} o_i|^2 \left\| \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} E_j^T E_j \left( \Psi(j)^{\top} \Psi(j) \right)^{-1} \right\|_\infty \leq 9C_s^{-1} 2^{j/2} n^{-1/2} \|V(j)\|_\infty^2.$$
Define $G_j^2 = 2\sigma^4 trA_j^2$. Note
\[
trA_j^2 = trW(j)^\top E_j^T E_j W(j) W(j)^\top E_j^T E_j = trE_j W(j) W(j)^\top E_j = trV_j^2
\]
so that $T_j^{(1)} = G_j^{-1} \sum_{i=1}^n a_{ii} (\xi_i^2 - \sigma^2)$. Condition (D.ii) implies $trA_j^2 \geq C_D 2^j \|V(j)\|_\infty^2$.

Since, by (D.iii), $\|V(j)\|_\infty \leq C_V$, it holds for every $\delta > 0$,
\[
P\left( \max_{j=0, \ldots, j(n)} T_j^{(1)} > \delta \right) \leq \sum_{j=0}^{j(n)} P\left( T_j^{(1)} > \delta \right) \\
\leq \delta^{-2} \sum_{j=0}^{j(n)} E\left| T_j^{(1)} \right|^2 \\
\leq \delta^{-2} \sum_{j=0}^{j(n)} G_j^{-2} \sigma^4 s_4 \sum_{i=1}^n a_{ii}^2 \\
\leq \delta^{-2} \sum_{j=0}^{j(n)} 2^{-1} C_D^{-1} 2^{-j} s_4 \|V(j)\|^{-2} n (9C_*^{-1} 2^j n^{-1} \|V(j)\|_\infty^2)^2 \\
\leq C\delta^{-2} n^{-1} 2^{(n)+1} \to 0, \quad n \to \infty.
\]

Next we consider $T_j^{(2)}$ which is obtained from $T_j'$ by removing the diagonal terms. This quadratic form can be approximated (in distribution) by a similar one with Gaussian errors $\tilde{\eta}_i$ at a reasonable rate provided that the corresponding value $C_A$, defined as $n$ times the ratio of the maximal diagonal element of the matrix $\sigma^4 A_j^2$ to $G_j^2 = 2\sigma^4 trA_j^2$, see (5.5) and Remark 5.1 in the Appendix, remains bounded.

The $i$-th diagonal element $d_i$ of $A_j^2$ is equal to $o_i^\top A_j^2 o_i$:
\[
d_i = o_i^\top A_j^2 o_i \\
= o_i^\top \left\{ \Psi(j)^\top (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} \Psi(j)^\top \right\}^2 o_i \\
= o_i^\top \Psi(j)^\top (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} \Psi(j) o_i.
\]

Clearly
\[
\left\| (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} \right\|_\infty \leq \left\| (\Psi(j)^\top \Psi(j)) \right\|_\infty^3 = \|V(j)^3\|_\infty.
\]

The use of (4.8) provides
\[
d_i \leq \|\Psi(j)^\top o_i\|^2 \left\| (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} E_j^T E_j (\Psi(j)^\top \Psi(j))^{-1} \right\|_\infty \\
\leq 9C_*^{-1} 2^j n^{-1} \|V(j)\|_\infty^3
\]
and similarly to the above

$$C_A := \max_{i=1,\ldots,n} nG^{-2}\sigma^4 \sum_{\ell=1}^{n} a_{i\ell}^2 \leq \frac{9C_s^{-1}\|V(j)\|_\infty^2 j}{2C_D^2\|V(j)\|_\infty^2} \leq \frac{9C_s^{-1}C_V}{2C_D}$$

that is, the value $C_A$ is bounded by a fixed constant depending on design regularity only.

By Corollary 5.8, the joint distribution of $T_j^{(2)}$, $j \leq j(n)$, and the distribution of their maximum, can be approximated by the distribution of similar quadratic forms of Gaussian r.v.'s which implies the required assertion.

## 5 Appendix

Here we briefly discuss some general properties of quadratic forms of random variables. We first consider the case when the underlying random variables are Gaussian and establish an exponential bound for deviations of such forms over certain level. Next we show how an arbitrary quadratic form of independent random variables can be approximated (in distribution) by a similar quadratic form of Gaussian random variables.

### 5.1 Deviation probabilities for quadratic forms of Gaussian random variables

Let $\varepsilon_1, \ldots, \varepsilon_N$ be Gaussian random variables with zero mean and the covariance $N \times N$ matrix $V$, i.e. $V = E\varepsilon\varepsilon^\top$ where $\varepsilon$ denotes the vector $\varepsilon = (\varepsilon_1, \ldots, \varepsilon_N)^\top$.

We first present the following general results about quadratic forms of Gaussian random variables.

**Proposition 5.1.** Let $\varepsilon_1, \ldots, \varepsilon_N$ be Gaussian random variables with zero mean and the covariance matrix $V := E\varepsilon\varepsilon^\top$. Then

$$E\|\varepsilon\|^2 := E\left(\varepsilon_1^2 + \ldots + E\varepsilon_N^2\right) = \text{tr}V,$$

$$E\left(\|\varepsilon\|^2 - \text{tr}V\right)^2 = 2\text{tr}V^2.$$  

Moreover, with $S_V^2 = 2\text{tr}V^2$, it holds for any $z \geq 0$

$$P\left(\pm \left(\|\varepsilon\|^2 - \sigma^2\text{tr}V\right) > z\sigma^2 S_V\right) \leq e^{-z^2/4} + e^{-zS_V/(6\|V\|_\infty)}.$$  

(5.1)

**Proof.** Normalizing by $\sigma^2$ allows to reduce the general case to the situation with $\sigma^2$ equal to 1, thus we assume for the rest of the proof that $\sigma^2 = 1$.

Let $V = U^\top \Lambda U$ be a diagonal representation of $V$ with a diagonal matrix $\Lambda = \text{diag}\{\lambda_1, \ldots, \lambda_N\}$ and an orthonormal matrix $U$. It is well known that $\zeta = \Lambda^{-1/2}U \varepsilon$ is a standard Gaussian vector and $\|\varepsilon\|^2 = \zeta^\top \Lambda \zeta$. Also it holds $\text{tr}V = \lambda_1 + \ldots + \lambda_N$, 

**SPOKOINY, V.**

29
\[ \text{tr}V^2 = \lambda_1^2 + \ldots + \lambda_N^2 \] and \( \|V\|_\infty = \max\{\lambda_1, \ldots, \lambda_N\} \). Hence, the expression \( \|\varepsilon\|^2 - \text{tr}V \) can be rewritten as follows:

\[
\|\varepsilon\|^2 - \text{tr}V = \xi^T U^T AU \xi - \text{tr}V = \xi^T \Lambda \xi - \text{tr}A = \lambda_1(\xi_1^2 - 1) + \ldots + \lambda_N(\xi_N^2 - 1),
\]

where \( \tilde{\xi} = U \xi \). Since \( U \) is orthonormal, and \( \xi \) is standard Gaussian, the vector \( \tilde{\xi} = U \xi \) is also standard normal, i.e. the \( \tilde{\xi}_i \)'s are i.i.d. \( \mathcal{N}(0, 1) \)-distributed.

For the proof of (5.1) we apply the exponential Chebyshev-inequality and utilize independence of the \( \tilde{\xi}_i \)'s: for an arbitrary positive number \( \mu \in (0, 1/(2\|V\|_\infty)) \)

\[
P\left( \sum_{i=1}^N \lambda_i(\tilde{\xi}_i^2 - 1) > zS_V \right) \leq \exp\{ -\mu z S_V \} \exp\left\{ \mu \sum_{i=1}^N \lambda_i(\tilde{\xi}_i^2 - 1) \right\}
= \exp\left\{ -\mu z S_V - \sum_{i=1}^N \left[ \mu \lambda_i + \frac{1}{2} \log(1 - 2\mu \lambda_i) \right] \right\} \quad (5.2)
\]

We now use the inequalities

\[
-\log(1 - u) \leq u + \frac{u^2}{2} + \frac{u^3}{3} + \frac{u^4}{4} + \frac{u^5}{5} + \frac{u^6}{6(1-u)} \leq u + u^2, \quad \forall u \in [0, 2/3],
-\log(1 - u) \leq u + u^2/2 \leq u + u^2, \quad \forall u \in [-2/3, 0].
\]

This implies for \( \mu \leq 1/(3\|V\|_\infty) \) and all \( i \):

\[
-\mu \lambda_i - 0.5 \log(1 - 2\mu \lambda_i) \leq 2\mu^2 \lambda_i^2
\]

and

\[
-\mu z S_V - \sum_{i=1}^N \left( \mu \lambda_i + \frac{1}{2} \log(1 - 2\mu \lambda_i) \right) \leq -\mu z S_V - \sum_{i=1}^N 2\mu^2 \lambda_i^2 = -\mu z S_V + \mu^2 S_V^2. \quad (5.3)
\]

If \( z \leq 2S_V/(3\|V\|_\infty) \) then select \( \mu = z/(2S_V) \). Under this choice the condition \( \mu \leq 1/(3\|V\|_\infty) \) is fulfilled and

\[
-\mu z S_V + \mu^2 S_V^2 = -z^2/4.
\]

For \( z > 2S_V/(3\|V\|_\infty) \) we pick \( \mu = 1/(3\|V\|_\infty) \), what provides

\[
-\mu z S_V + \mu^2 S_V^2 = -\frac{z S_V}{3\|V\|_\infty} + \frac{S_V^2}{(3\|V\|_\infty)^2} = -\frac{S_V}{3\|V\|_\infty} \left( z - \frac{S_V}{3\|V\|_\infty} \right) \leq -\frac{z S_V}{6\|V\|_\infty}.
\]

Now (5.2) and (5.3) imply

\[
P\left( \|\varepsilon\|^2 - \sigma^2 \text{tr}V > z\sigma^2 S_V \right) \leq \max\left\{ e^{-z^2/4}, e^{-zS_V/(6\|V\|_\infty)} \right\} \leq e^{-z^2/4} + e^{-zS_V/(6\|V\|_\infty)}.
\]

Since all the above calculations remain valid for negative \( \lambda_i \), the same bound holds for \(- (\|\varepsilon\|^2 - \sigma^2 \text{tr}V) \) and (5.1) follows. \( \square \)
Further, for a deterministic vector \( c = (c_1, \ldots, c_N)^T \) from \( \mathbb{R}^N \), we consider quadratic forms of type
\[
\|c + \varepsilon\|^2 = |c_1 + \varepsilon_1|^2 + \ldots + |c_N + \varepsilon_N|^2.
\]

**Proposition 5.2.** Let \( \varepsilon_1, \ldots, \varepsilon_N \) be Gaussian random variables with zero mean and the covariance matrix \( V \). Then it holds for any vector \( c = (c_1, \ldots, c_N)^T \) in \( \mathbb{R}^N \)
\[
E\|c + \varepsilon\|^2 = \|c\|^2 + \text{tr}V.
\]
\[
\text{Var}\|c + \varepsilon\|^2 := E\left(\|c + \varepsilon\|^2 - \|c\|^2 - \text{tr} V\right)^2 = 4c^T V c + 2\text{tr}V^2,
\]
\[
E\left(\|c + \varepsilon\|^2 - \text{tr}V\right)^2 = \|c\|^4 + 4c^T V c + 2\text{tr}V^2 \leq \|c\|^4 + 4\|c\|^2\sqrt{\text{tr}V^2} + 2\text{tr}V^2.
\]

Moreover, with \( S_V^2 = 2\text{tr}V^2 \), for every positive \( \gamma \)
\[
P\left(\pm(\|c + \varepsilon\|^2 - \|c\|^2 - \text{tr}V) > \gamma\|c\|S_{V}^{1/2} + \gamma S_V\right) \leq 2e^{-\gamma^2/4} + e^{-\gamma S_V/(6\|V\|_\infty)}.
\]

**Proof.** With vector notation, the studied quadratic form can be rewritten as \( \|c + \varepsilon\|^2 = (c + \varepsilon)^T(c + \varepsilon) \). Now, since \( E\varepsilon_i = 0 \), it holds
\[
E\|c + \varepsilon\|^2 = E\left(\|c\|^2 + 2c^T \varepsilon + \|\varepsilon\|^2\right) = \|c\|^2 + E\|\varepsilon\|^2 = \|c\|^2 + \text{tr}V.
\]

Next,
\[
\text{Var}\|c + \varepsilon\|^2 = E\left(\|c + \varepsilon\|^2 - \|c\|^2 - \|c + \varepsilon\|^2\right)^2
\]
\[
= E\left(2c^T \varepsilon + \|\varepsilon\|^2 - \text{tr}V\right)^2
\]
\[
= 4E|c^T \varepsilon|^2 + 4Ec^T \varepsilon \left(\|\varepsilon\|^2 - \text{tr}V\right) + Ec^T \left(\|\varepsilon\|^2 - \text{tr}V\right)^2.
\]

The Gaussian vector \( \varepsilon \sim \mathcal{N}(0, V) \) fulfills
\[
E\varepsilon (\|\varepsilon\|^2 - \text{tr}V) = 0, \quad \text{and} \quad E|c^T \varepsilon|^2 = c^T (Ec \varepsilon) c = c^T V c
\]
so that in view of Proposition 5.1 \( \text{Var}\|c + \varepsilon\|^2 = 4c^T V c + 2\text{tr}V^2 \) as required. Similarly one obtains
\[
E\left(\|c + \varepsilon\|^2 - \text{tr}V\right)^2 = \|c\|^4 + 4c^T V c + 2\text{tr}V^2
\]
and by the Cauchy-Schwarz inequality \( c^T V c \leq \|c\|^2\sqrt{\text{tr}V^2} \).

Note that the scalar product \( c^T \varepsilon \) is a linear combination of the Gaussian zero mean random variables and it is therefore Gaussian as well with \( Ec^T \varepsilon = 0 \) and \( E|c^T \varepsilon|^2 = c^T V c \). This yields for every \( \gamma \geq 0 \)
\[
P\left(c^T \varepsilon > \gamma \sqrt{c^T V c}\right) \leq e^{-\gamma^2/2}.
\]
The condition $\|V\|_\infty \leq \sqrt{\text{tr}V^2}/2$ provides $c^\top V c \leq \|c\|^2\|V\|_\infty \leq \|c\|^2\sqrt{\text{tr}V^2}/2$. Combining this inequality with the previous one implies

$$P\left(2c^\top \varepsilon > \gamma \|c\|S_V^{1/2}\right) \leq e^{-\gamma^2/4}.$$

Next, by Proposition 5.1

$$P\left(\|\varepsilon\|^2 - \text{tr}V > \gamma S_V\right) \leq e^{-\gamma^2/4} + e^{-\gamma S_V/(6\|V\|_\infty)}.$$

Summing up the above estimates yields

$$P\left(\|c + \varepsilon\|^2 - \text{tr}V > \|c\|^2 + \gamma \|c\|S_V^{1/2} + \gamma S_V\right) = P\left(2c^\top \varepsilon + \|\varepsilon\|^2 - \text{tr}V > \gamma \|c\|S_V^{1/2} + \gamma S_V\right) \leq P\left(2c^\top \varepsilon > \gamma \|c\|S_V^{1/2}\right) + P\left(\|\varepsilon\|^2 - \text{tr}V > \gamma S_V\right) \leq 2e^{-\gamma^2/4} + e^{-\gamma S_V/(6\|V\|_\infty)}$$

as required. The expression $-\left(\|c + \varepsilon\|^2 - \text{tr}V\right)$ can be considered similarly.

The next technical result bounds the density of a standardized quadratic form $Q = \sum_{i=1}^N \sum_{j=1}^N a_{ij} \varepsilon_i \varepsilon_j = \varepsilon^\top A \varepsilon$ with a symmetric matrix $A$ and i.i.d. standard normal $\varepsilon_i$’s.

**Lemma 5.3.** Let $Q = \sum_{i=1}^N \sum_{j=1}^N a_{ij} \varepsilon_i \varepsilon_j$ with independent standard normal r.v.’s $\varepsilon_i$ and with the coefficients $a_{ij}$ satisfying $\sum_i \sum_j a_{ij}^2 = 1$. For every $x_0 > 0$ there exists $C(x_0) > 0$ such that the density $p(x)$ of $Q$ fulfills $p(x) \leq C(x_0)$ for all $x \geq x_0$. Moreover, if $\|A^2\|_\infty \leq 1/6$, then $p(x)$ is uniformly bounded by an absolute constant $C_0$.

**Proof.** Change-of-basis arguments allow to reduce the assertion to the case of a diagonal quadratic form $Q = \sum_{i=1}^N \lambda_i \varepsilon_i^2$ with $\sum_i \lambda_i^2 = 1$. We consider in details only the case when $\|A^2\|_\infty = \max_i \lambda_i^2 \leq 1/6$.

The characteristic function $f(t)$ of $S$ obviously fulfills

$$f(t) := E e^{itS} = \prod_{i=1}^N (1 - 2i \lambda_i t)^{-1/2} \quad \text{and} \quad |f(t)| = \prod_{i=1}^N (1 + 4\lambda_i^2 t^2)^{-1/4}$$

where $t = \sqrt{-1}$. The conditions $\lambda_i^2 \leq 1/6$ and $\sum_i \lambda_i^2 = 1$ ensure that all the $\lambda_i$’s can be distributed into three groups, say $\Pi_1$, $\Pi_2$ and $\Pi_3$ such that $\sum_{i \in \Pi_j} \lambda_i^2 \geq 1/6$ for $j = 1, 2, 3$. Then

$$|f(t)|^{-1} = \prod_{i=1}^N (1 + 4\lambda_i^2 t^2) \geq \prod_{j=1}^3 \left(1 + \sum_{i \in \Pi_j} 4\lambda_i^2 t^2\right) \geq (1 + 2t^2/3)^3$$

and the assertion follows in view of

$$p(x) = (2\pi)^{-1} \int_{-\infty}^\infty e^{-itx} f(t) dt \leq (2\pi)^{-1} \int_{-\infty}^\infty |f(t)| dt \leq (2\pi)^{-1} \int_{-\infty}^\infty (1 + 2t^2/3)^{-3/4} dt < \infty.$$
5.2 Gaussian approximation for quadratic forms

In what follows we consider quadratic forms $\sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \xi_i \xi_\ell$ of independent but not necessarily normal random variables $\xi_1, \ldots, \xi_n$ with vanishing diagonal coefficients, i.e. $a_{ii} = 0$. We aim to show that, under moment conditions on $\xi_i$’s and mild assumptions on the coefficients of the quadratic form, the asymptotic distribution of this quadratic form only weakly depends on the particular distribution of $\xi_i$’s and, as a consequence, it can be approximated by a distribution of a similar quadratic form of Gaussian r.v.’s with the same first and second moments.

Let $A = (a_{i\ell}, i, \ell = 1, \ldots, n)$ be a $n \times n$ symmetric matrix with $a_{ii} = 0$ for all $i$, and let $\xi_1, \ldots, \xi_n$ be independent zero mean r.v.’s with $E \xi_i^4 < \infty$ for all $i$. Define $a_{i}^2 = E \xi_i^2$. We study some properties of the quadratic form $\sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \xi_i \xi_\ell$.

**Lemma 5.4.** It holds

$$E \sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \xi_i \xi_\ell = \sum_{i=1}^{n} a_{ii} \sigma_i^2 = 0,$$

$$E \left\{ \sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \xi_i \xi_\ell \right\}^2 = 2 \sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell}^2 \sigma_i^2 \sigma_\ell^2. \quad (5.4)$$

**Proof.** Obvious. Here it is only important that the diagonal elements $a_{ii}$ vanish. \quad \Box

Let $\tilde{\xi}_1, \ldots, \tilde{\xi}_n$ be a sequence of independent Gaussian r.v.’s with $E \tilde{\xi}_i^2 = E \xi_i^2 = 0$ and $E \tilde{\xi}_i^2 = E \xi_i^2 = a_{i}^2$, $i = 1, \ldots, n$. Denote

$$A(\xi_1, \ldots, \xi_n) = \sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \xi_i \xi_\ell \quad \text{and} \quad A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) = \sum_{i=1}^{n} \sum_{\ell=1}^{n} a_{i\ell} \tilde{\xi}_i \tilde{\xi}_\ell.$$  

Clearly $E A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) = 0$ and $E |A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n)|^2 = E |A(\xi_1, \ldots, \xi_n)|^2$.

**Proposition 5.5.** Let $E \xi_i^4 \leq C_4 a_i^4$ for some fixed constant $C_4 \geq 3$. Let, for a symmetric matrix $A$ with $a_{ii} = 0$ for $i = 1, \ldots, n$, constants $G$ and $C_A$ fulfill

$$\max_{i=1, \ldots, n} n G^{-2} \sum_{\ell=1}^{n} a_{i\ell}^2 \sigma_i^2 \sigma_\ell^2 \leq C_A. \quad (5.5)$$

Then, for every three times continuously differentiable function $f$ with $f_3 = \sup_x |f'''(x)| < \infty$, it holds

$$|E f \left( G^{-1} A(\xi_1, \ldots, \xi_n) \right) - E f \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right)| \leq (8/3) f_3 (C_4 C_A)^{3/2} n^{-1/2}.$$

**Remark 5.1.** The value $C_A$ can be easily evaluated for the case of an homogeneous noise when all $\sigma_i^2$ coincide with some $\sigma^2$. Clearly each sum $d_i = \sum_{\ell=1}^{n} a_{i\ell}^2$ is $i$-th diagonal element of $A^2$ and (5.5) meets with $C_A = n G^{-2} \sigma^4 \max_{i=1, \ldots, n} d_i$. 

Remark 5.2. The conditions of Proposition 5.5 do not guarantee that the distribution of $G^{-1}A(\xi_1, \ldots, \xi_n)$ is close to some normal distribution. A typical example which just meets in hypothesis testing framework corresponds to the quadratic form $A(\xi_1, \ldots, \xi_n) = (\xi_1 + \ldots + \xi_n)^2 - (\xi_1^2 + \ldots + \xi_n^2)$, which, being standardized, is nearly centered $\chi^2$.

Proof. By change $\xi_i$ into $\xi_i/\sigma_i$ and $a_{i\ell}$ into $a_{i\ell}\sigma_i\sigma_\ell$ the general case can be reduced to the situation with $\sigma_i = 1$ for all $i$. Hence, for the sake of notation simplicity, we suppose that $\sigma_i^2 = 1$, $i = 1, \ldots, n$.

We use the following obvious inequality

$$
\left| \mathbb{E} f \left( G^{-1}A(\xi_1, \ldots, \xi_n) \right) - \mathbb{E} f \left( G^{-1}A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) \right|
\leq \sum_{i=1}^n \left| \mathbb{E} f \left( G^{-1}A(\xi_1, \ldots, \xi_i, \tilde{\xi}_{i+1}, \ldots, \tilde{\xi}_n) \right) - \mathbb{E} f \left( G^{-1}A(\xi_1, \ldots, \xi_{i-1}, \tilde{\xi}_i, \tilde{\xi}_{i+1}, \ldots, \tilde{\xi}_n) \right) \right|
$$

where we assume $\xi_0 = \tilde{\xi}_{n+1} = 0$. We evaluate the last summand here, the other can be bounded in the same way. Denote

$$u_{n-1} = G^{-1} \sum_{i=1}^{n-1} \sum_{\ell=1}^{n-1} a_{i\ell} \xi_i \xi_\ell,$$

$$\Delta_n = G^{-1}A(\xi_1, \ldots, \xi_n) - u_{n-1} = 2G^{-1} \xi_n \sum_{i=1}^{n-1} a_{in} \xi_i,$$

$$\tilde{\Delta}_n = G^{-1}A(\xi_1, \ldots, \xi_{n-1}, \tilde{\xi}_n) - u_{n-1} = 2G^{-1} \xi_n \sum_{i=1}^{n-1} a_{in} \xi_i.$$

The Taylor expansion yields

$$
\left| \mathbb{E} f \left( G^{-1}A(\xi_1, \ldots, \xi_n) \right) - \mathbb{E} f \left( G^{-1}A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) \right|
\leq \left| \mathbb{E} f'(u_{n-1})(\Delta_n - \tilde{\Delta}_n) \right| + \frac{1}{2} \left| \mathbb{E} f''(u_{n-1})(\Delta_n^2 - \tilde{\Delta}_n^2) \right| + \frac{f_3}{6} (\mathbb{E} |\Delta_n|^3 + \mathbb{E} |\tilde{\Delta}_n|^3)
$$

Since $\xi_n$ and $\tilde{\xi}_n$ are independent of $\xi_1, \ldots, \xi_{n-1}$ and since $\mathbb{E} \xi_n = \mathbb{E} \tilde{\xi}_n = 0$, $\mathbb{E} \xi_n^2 = \mathbb{E} \tilde{\xi}_n^2 = 1$, taking the conditional expectation given $\xi_1, \ldots, \xi_{n-1}$, we obtain

$$
\mathbb{E} \left( \Delta_n - \tilde{\Delta}_n \mid \xi_1, \ldots, \xi_{n-1} \right) = 0, \quad \mathbb{E} \left( \Delta_n^2 - \tilde{\Delta}_n^2 \mid \xi_1, \ldots, \xi_{n-1} \right) = 0. \quad (5.7)
$$

Further we evaluate $\mathbb{E} |\Delta_n|^3$ and $\mathbb{E} |\tilde{\Delta}_n|^3$. Note first that, since $\mathbb{E} \xi_n^4 \leq C_4$ with $C_4 \geq 3$,

$$
\mathbb{E} \left( \sum_{i=1}^{n-1} a_{in} \xi_i \right)^4 \leq \sum_{i=1}^{n-1} a_{in}^4 \mathbb{E} \xi_i^4 + 3 \sum_{i=1}^{n-1} a_{in}^2 a_{in}^2 \leq \sum_{i=1}^{n-1} a_{in}^4 (C_4 - 3) + 3 \left( \sum_{i=1}^{n-1} a_{in}^2 \right)^2 \leq C_4 \left( \sum_{i=1}^{n-1} a_{in}^2 \right)^2.
$$
Now the Hölder inequality yields in view of $E|\xi_n|^3 \leq C_4^{3/4}$

$$G^3 E|\Delta_n|^3 = E|\xi_n|^3 E \left| 2 \sum_{i=1}^{n-1} a_{in} \xi_i \right|^3 \leq 8 C_4^{3/4} \left\{ E \left( \sum_{i=1}^{n-1} a_{in} \xi_i \right)^4 \right\}^{3/4} \leq 8 C_4^{3/2} \left( \sum_{i=1}^n a_{i,n}^2 \right)^{3/2}$$

and the condition $G^{-2} \sum_{i=1}^n a_{i,n}^2 \leq n^{-1} C_A$ provides

$$E|\Delta_n|^3 \leq 8(C_4 C_A)^{3/2} n^{-3/2}. \tag{5.8}$$

For the expression $\tilde{\Delta}$ with a Gaussian r.v. $\tilde{\xi}_n$, the similar bound applies:

$$E|\tilde{\Delta}_n|^3 \leq 8(C_4 C_A)^{3/2} n^{-3/2}. \tag{5.9}$$

Substituting these estimates as well as (5.7) in (5.6) implies

$$\left| E f \left( G^{-1} A(\xi_1, \ldots, \xi_n) \right) - E f \left( G^{-1} A(\xi_1, \ldots, \xi_{n-1}, \tilde{\xi}_n) \right) \right| \leq \frac{16}{6} f_3(C_4 C_A)^{3/2} n^{-3/2}. $$

Similar bounds hold for the other summands in (5.6). Summing them out, we obtain

$$\left| E f \left( G^{-1} A(\xi_1, \ldots, \xi_n) \right) - E f \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) \right| \leq \frac{8}{3} f_3(C_4 C_A)^{3/2} n^{-1/2}$$

as required.

**Corollary 5.6.** Under the conditions of Proposition 5.5, for each $\delta > 0$ and every $x$

$$P \left( G^{-1} A(\xi_1, \ldots, \xi_n) > x \right) \leq P \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) > x - \delta \right) + C C_4^{3/2} n^{-1/2} \delta^{-3}$$

with a constant $C$ depending on $C_4$ only. If, in addition, $G^2 \geq E[A(\xi_1, \ldots, \xi_n)]^2$, then for every $x_0 > \delta$ and all $x \geq x_0$

$$P \left( G^{-1} A(\xi_1, \ldots, \xi_n) > x \right) \leq P \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) > x \right) + C C_4^{3/2} n^{-1/2} \delta^{-3} + C(x_0) \delta$$

with some fixed constant $C(x_0)$.

**Proof.** Let a smooth nondecreasing function $f$ fulfill $f(u) = 0$ for $u \leq -1$ and $f(u) = 1$ for $u \geq 0$. Define $C_f = \sup_u |f''(u)|$. Now, given $x$ and $\delta > 0$, set $f_{x,\delta}(u) = f(\delta(1-u)-x))$. Obviously $f_{x,\delta}(u) = 0$ for $u \leq x - \delta$, $f_{x,\delta}(u) = 1$ for $u \geq x$, $0 \leq f_{x,\delta}(u) \leq 1$ and also $|f''_{x,\delta}(u)| \leq C_f \delta^{-3}$ for all $u$.

Next, by Proposition 5.5

$$P \left( G^{-1} A(\xi_1, \ldots, \xi_n) > x \right) \leq E f_{x,\delta} \left( G^{-1} A(\xi_1, \ldots, \xi_n) \right)$$

$$\leq E f_{x,\delta} \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) + \frac{8}{3} (C A C_4)^{3/2} C_f \delta^{-3} n^{-1/2}.$$  

It remains to note that

$$E f_{x,\delta} \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) \leq P \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) > x - \delta \right).$$

By Lemma 5.3, for every $G$ with $G^2 \geq E[A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n)]^2$, the density of $G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n)$ is uniformly in $x \geq x_0$ bounded and the last statement of the corollary follows. □
5.3 A family of quadratic forms

Here we briefly discuss the situation arising in adaptive testing problem when the maximum of a family of quadratic forms of \( \xi_i \)'s is considered. We again aim to show that the joint distribution of this family (and thus the distribution of the maximum) can be well approximated by the similar distribution of quadratic forms of Gaussian random variables.

Let \( A_1, \ldots, A_M \) be a collection of symmetric \( n \times n \)-matrices with vanishing diagonal elements. We analyze the joint distribution of the standardized quadratic forms \( G_m^{-1} A_m(\xi_1, \ldots, \xi_n) \) with independent random variables \( \xi_i \) satisfying \( \mathbf{E} \xi_i = 0, \sigma_i^2 \) and \( \mathbf{E} \xi_i^2 < \infty \), and some constants \( G_m, m = 1, \ldots, M \). More precisely, we intend to show that the distribution of this family is close to the distribution of the family \( \{ G_m^{-1} A_m(\tilde{\xi}_1, \ldots, \tilde{\xi}_n), m = 1, \ldots, M \} \) with Gaussian variables \( \tilde{\xi}_i \sim N(0, \sigma^2) \).

**Proposition 5.7.** Let the variables \( \xi_i \) fulfill \( \mathbf{E} \xi_i^4 \leq C_E \sigma_i^4 \) and let every matrix \( A_m \) satisfy the conditions of Proposition 5.5 with the same constant \( C_A \), \( m = 1, \ldots, M \). Then, for every three times continuously differentiable function \( f \) in the space \( \mathbb{R}^M \), it holds

\[
\left| \mathbf{E} f \left( G^{-1} A(\xi_1, \ldots, \xi_n) \right) - \mathbf{E} f \left( G^{-1} A(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) \right) \right| \leq \frac{8}{3} f_3 M^3 (C_A C_A)^{3/2} n^{-1/2}
\]

where \( G^{-1} A \) denotes the vector with elements \( G_m^{-1} A_m \) and \( f_3 \) means the maximum of the absolute value of the third derivative of \( f \), that is,

\[
f_3 = \sup_{x \in \mathbb{R}^M} \max_{i,j,k=1,\ldots,M} \left| \frac{\partial^3 f(x)}{\partial x_i \partial x_j \partial x_k} \right|.
\]

**Proof.** The proof follows the same line as in the case of one quadratic forms when understanding \( G^{-1} A, u_{n-1}, f'(u_{n-1}) \) and \( \Delta_n \) as vectors in \( \mathbb{R}^M \) and \( f''(u_{n-1}) \) as the \( M \times M \)-matrix of the second derivatives of \( f \) at \( u_{n-1} \). The only difference is that we apply the bound \( \mathbf{E} |\Delta_n|^3 \leq M^3 8 (C_A C_A)^{3/2} n^{-3/2} \) for the norm of \( \Delta_n \) which is \( M^3 \) times larger than in the case of \( M = 1 \), cf. (5.8). The details are left to the reader. \( \square \)

A straightforward corollary of this results concerns the maximum of \( G_m^{-1} A_m \)'s.

**Corollary 5.8.** Let the conditions of Proposition 5.7 be fulfilled. Then for any \( x \geq \delta \)

\[
P \left( \max_{m \leq M} G_m^{-1} A_m(\xi_1, \ldots, \xi_n) > x \right) \leq P \left( \max_{m \leq M} G_m^{-1} A_m(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) > x - \delta \right) + C M^3 C_A^{3/2} n^{-1/2} \delta^{-3}
\]

with a constant \( C \) depending on \( C_A \) only. If, in addition, \( G_m^2 \geq \mathbf{E} |A_m(\xi_1, \ldots, \xi_n)|^2 \) for all \( m \leq M \), then for every \( x_0 > \delta \) and all \( x \geq x_0 \)

\[
P \left( \max_{m \leq M} G_m^{-1} A_m(\xi_1, \ldots, \xi_n) > x \right) \leq P \left( \max_{m \leq M} G_m^{-1} A_m(\tilde{\xi}_1, \ldots, \tilde{\xi}_n) > x \right) + C M^3 C_A^{3/2} n^{-1/2} \delta^{-3} + M \delta C(x_0)
\]
Proof. The first statement can be checked exactly as for the case of $M = 1$, see the proof of Corollary 5.6. As regards to the second statement, it suffices to mention that the density of each $G_{m}^{-1}A_{m}(\tilde{\xi}, \ldots, \tilde{\xi}_{n})$ is bounded by $C(x_{0})$ for all $x \geq x_{0}$ and hence the density of the maximum of the $G_{m}^{-1}A_{m}(\tilde{\xi}, \ldots, \tilde{\xi}_{n})$’s is bounded by $MC(x_{0})$.

Remark 5.3. If $M$ is not too large in the sense that $M^{3}n^{-1/2}$ is small, then, selecting a proper $\delta$, we can derive from this statement that the distribution of the maximum of $G_{m}^{-1}A_{m}(\xi, \ldots, \xi)’s$ is approximated by the similar distributions for $G_{m}^{-1}A_{m}(\tilde{\xi}, \ldots, \tilde{\xi})$’s.
