An enumerative formula for the spherical cap discrepancy

Holger Heitsch, René Henrion

Abstract

The spherical cap discrepancy is a widely used measure for how uniformly a sample of points on the sphere is distributed. Being hard to compute, this discrepancy measure is typically replaced by some lower or upper estimates when designing optimal sampling schemes for the uniform distribution on the sphere. In this paper, we provide a fully explicit, easy to implement enumerative formula for the spherical cap discrepancy. Not surprisingly, this formula is of combinatorial nature and, thus, its application is limited to spheres of small dimension and moderate sample sizes. Nonetheless, it may serve as a useful calibrating tool for testing the efficiency of sampling schemes and its explicit character might be useful also to establish necessary optimality conditions when minimizing the discrepancy with respect to a sample of given size.

1 Introduction

A discrepancy measure $\Delta(\mu, \nu)$ quantifies the deviation between two given measures μ and ν . On a local scale, one may compare the two measures with respect to a given set B to obtain the so-called local discrepancy

$$\Delta(B; \mu, \nu) := |\mu(B) - \nu(B)|.$$

In order to arrive at a global deviation measure, one extends the comparison of the two measures to a collection \mathcal{B} of sets and chooses an appropriate L_p norm:

$$\begin{aligned} \Delta_p(\mu, \nu) &:= \left(\int_{\mathcal{B}} \Delta(B; \mu, \nu)^p d\omega(B) \right)^{1/p} \quad (p < \infty), \\ \Delta_\infty(\mu, \nu) &:= \sup_{B \in \mathcal{B}} \Delta(B; \mu, \nu). \end{aligned} \tag{1}$$

For surveys on discrepancies, we refer to, e.g., [2, 4, 10]. Discrepancies play a fundamental role in many mathematical disciplines. For instance, in stochastic programming, the stability of optimal solutions and optimal values with respect to perturbations of the underlying probability measure can be expected only for a problem-adapted choice of a discrepancy [11].

The focus of the present paper will be on the so-called *spherical cap discrepancy*. Our interest in this quantity comes from the algorithmic solution of optimization problems subject to probabilistic constraints. One approach here relies on the so-called *spheric-radial decomposition* of random vectors having elliptically symmetric distribution (e.g., Gaussian). This approach allows for a representation of the decision-dependent probability of some random inequality system as well as of its gradient as integrals with respect to the uniform distribution on a sphere [12]. Hence, for an efficient numerical approximation of these integrals by finite sums, one has to make use of low discrepancy samples for that distribution. It is well known (see, e.g. [1, p. 991]), that the resulting integration error tends to zero (for samples of increasing size) if and only if the spherical cap discrepancy associated with these samples tends to zero. This special discrepancy is obtained from our general setting (1) by defining

$p := \infty$, μ as the uniform measure on the sphere, ν as the empirical measure induced by the sample and \mathcal{B} as the collection of all closed half spaces intersected with the sphere (caps). To be more precise, we define the closed halfspace $H(w, t)$ parameterized by (w, t) , its empirical and cap measures $\mu^{emp}(w, t)$ and $\mu^{cap}(w, t)$, respectively, and the spherical cap discrepancy Δ associated with the sample $\{x^1, \dots, x^N\}$ by

$$\begin{aligned} H(w, t) &:= \{x \in \mathbb{R}^n \mid \langle w, x \rangle \geq t\} \quad (w \in \mathbb{S}^{n-1}, t \in [-1, 1]), \\ \mu^{emp}(w, t) &:= N^{-1} \cdot \#\{i \in \{1, \dots, N\} \mid x^i \in H(w, t)\}, \\ \mu^{cap}(w, t) &:= \mu(\mathbb{S}^{n-1} \cap H(w, t)) \quad (\mu = \text{law of uniform distribution on } \mathbb{S}^{n-1}), \\ \Delta(w, t) &:= |\mu^{emp}(w, t) - \mu^{cap}(w, t)|, \\ \Delta &:= \sup_{w \in \mathbb{S}^{n-1}, t \in [-1, 1]} \Delta(w, t). \end{aligned}$$

The following explicit formula for the cap measure - not depending on $w \in \mathbb{S}^{n-1}$ - is well known

$$\mu^{cap}(w, t) = C_n \cdot \begin{cases} \int_0^{\arccos(t)} \sin^{n-2}(\tau) d\tau, & \text{if } 0 \leq t \leq 1, \\ 1 - \int_0^{\arccos(-t)} \sin^{n-2}(\tau) d\tau, & \text{if } -1 \leq t < 0, \end{cases} \quad (2)$$

where

$$C_n := \frac{1}{\int_0^\pi \sin^{n-2}(\tau) d\tau}$$

is the normalizing constant.

Figure 1: Examples for spherical caps

Figure 1 illustrates different spherical caps on \mathbb{S}^2 for a set of three points located in the x/y plane. This plane itself induces an upper and a lower closed halfspace each of them containing all three points (left picture). Hence, the associated upper and lower caps both have empirical measure 1 and cap measure $1/2$. Therefore, the local discrepancies $\Delta(w, t)$ of these caps equal $1/2$. Another hyperplane passes just through two of the three points (right picture) and the associated left and right halfspaces induce a big and a small cap. The measure of the small cap tends to zero when the two points converge to $-x_1$. Therefore, the local discrepancy related with this small cap tends to $2/3$.

To the best of our knowledge, no explicit formula for calculating the spherical cap discrepancy has been known so far. Rather the emphasis in the literature has been laid on suitable estimates with

respect to more manageable quantities allowing for asymptotic derivations and constructions of efficient low discrepancy designs (see, e.g., [1, 7]). On the other hand, beyond the asymptotic ‘large sample’ viewpoint it might be of some interest even for fixed moderate sample sizes to establish an easy enumerative formula enabling one to precisely compute the discrepancy and to compare different sampling schemes.

As a rule, L_p discrepancies ($p < \infty$) are easier to compute than L_∞ discrepancies as a consequence of the collection \mathcal{B} of test sets typically having infinite cardinality [3]. As far as explicit formulae for L_∞ discrepancies are available (e.g., for rectangular or general polyhedral sets, see [3, 8, 9]), they are of combinatorial nature which limits their application with respect to the dimension and the size of the sample. More precisely, it has been shown in [6], that computing the star discrepancy is an NP-hard problem. Moreover, the result is improved by [5] who proved that it is indeed W[1]-hard. Therefore, it is not surprising that a similar combinatorial aspect shows up in the enumerative formula for the spherical cap discrepancy we present in Theorem 1 below. In our numerical experiments, we apply the formula to spheres of dimension starting from 2 (2000 samples) up to 5 (100 samples). Even in this rather modest setting, the formula may prove useful for calibration purposes with respect to some given sampling scheme. For instance, in [1, p. 1005] an easy to compute lower bound for the spherical cap discrepancy is used in numerical experiments in order to confirm empirically a certain asymptotic order for a digital net based on a two-dimensional Sobol’ point set on \mathbb{S}^2 . Strictly speaking, the order obtained with respect to the lower bound transfers to the discrepancy only when the ratio between the true value and the lower estimate is approximately constant for increasing sample size. This is what we may confirm indeed in our numerical experiments. We also use the proven formula in order to directly compare discrepancies of a few sampling schemes on \mathbb{S}^2 for sample sizes of up to 1000. The results verify the good quality of a sampling scheme via Lambert’s equal-area transform proposed in [1, p. 995]. Finally, we mention that the explicit character of the obtained formula might be of some interest for the derivation of necessary optimality conditions when minimizing the discrepancy as a function of a sample of fixed size.

2 Preparatory Results

We have the following elementary (semi-) continuity properties of both considered measures:

Lemma 1. μ^{cap} is continuous and μ^{emp} is upper semicontinuous on $\mathbb{S}^{n-1} \times [-1, 1]$. Moreover, the following relations are satisfied for all $w \in \mathbb{S}^{n-1}$ and $t \in [-1, 1]$:

$$\begin{aligned} \mu^{emp}(w, t) + \mu^{emp}(-w, -t) &= \\ 1 + N^{-1} \#\{i | x^i \in H(w, t) \cap H(-w, -t)\} &\geq 1, \end{aligned} \quad (3)$$

$$\mu^{cap}(w, t) + \mu^{cap}(-w, -t) = 1. \quad (4)$$

Proof. The continuity of μ^{cap} and (4) follow immediately from (2), while (3) is an immediate consequence of the definitions. Let $w \in \mathbb{S}^{n-1}$, $t \in [-1, 1]$ and $(w_k, t_k) \rightarrow (w, t)$ an arbitrary sequence with $w_k \in \mathbb{S}^{n-1}$, $t_k \in [-1, 1]$. Define

$$I := \{i \in \{1, \dots, N\} | x^i \notin H(w, t)\},$$

so that $\langle w, x^i \rangle < t$ for all $i \in I$. Then, by continuity, there is some k_0 , such that $\langle w_k, x^i \rangle < t_k$ - i.e., $x^i \notin H(w_k, t_k)$ - for all $k \geq k_0$ and all $i \in I$. It follows that

$$\mu^{emp}(w_k, t_k) \leq \mu^{emp}(w, t) \quad \forall k \geq k_0,$$

whence

$$\limsup_{k \rightarrow \infty} \mu^{emp}(w_k, t_k) \leq \mu^{emp}(w, t).$$

This proves the upper semicontinuity of μ^{emp} on $\mathbb{S}^{n-1} \times [-1, 1]$. \square

Figure 2 plots the local discrepancy $\Delta(w, t)$ for the unit circle \mathbb{S}^1 . As can be seen, it is a highly irregular, discontinuous (actually neither upper nor lower semicontinuous yet piecewise smooth) function. Therefore it is not $\tilde{\text{A}}$ priori evident that the supremum in the definition of the discrepancy is attained.

Figure 2: Plot of $\Delta(w, t)$ for a sample of size $N = 1$ (left) and $N = 5$ (right) on \mathbb{S}^1 .

The next proposition shows that the discrepancy Δ is always realized indeed by a certain cap:

Proposition 1. *There are $w^* \in \mathbb{S}^{n-1}$, $t^* \in [-1, 1]$, such that*

$$\Delta = |\mu^{emp}(w^*, t^*) - \mu^{cap}(w^*, t^*)|.$$

Proof. Let $(w_k, t_k) \in \mathbb{S}^{n-1} \times [-1, 1]$ be a sequence realizing the supremum in the definition of Δ :

$$|\mu^{emp}(w_k, t_k) - \mu^{cap}(w_k, t_k)| \rightarrow_k \Delta \quad (5)$$

By the compactness of $\mathbb{S}^{n-1} \times [-1, 1]$ we may assume that

$$(w_k, t_k) \rightarrow (\bar{w}, \bar{t}) \in \mathbb{S}^{n-1} \times [-1, 1]. \quad (6)$$

According to (5) one may assume one of the following two cases upon passing to a subsequence:

$$\mu^{emp}(w_k, t_k) - \mu^{cap}(w_k, t_k) \rightarrow \Delta, \quad (7)$$

$$\mu^{cap}(w_k, t_k) - \mu^{emp}(w_k, t_k) \rightarrow \Delta. \quad (8)$$

In the case of (7), the continuity of μ^{cap} and the upper semicontinuity of μ^{emp} on $\mathbb{S}^{n-1} \times [-1, 1]$ (see Lemma 1) yield along with (6) that:

$$\begin{aligned} \Delta &= \lim_{k \rightarrow \infty} (\mu^{emp}(w_k, t_k) - \mu^{cap}(w_k, t_k)) \\ &= \limsup_{k \rightarrow \infty} (\mu^{emp}(w_k, t_k) - \mu^{cap}(w_k, t_k)) \\ &\leq \mu^{emp}(\bar{w}, \bar{t}) - \mu^{cap}(\bar{w}, \bar{t}) \leq |\mu^{emp}(\bar{w}, \bar{t}) - \mu^{cap}(\bar{w}, \bar{t})| \leq \Delta. \end{aligned}$$

Hence, $\Delta = |\mu^{emp}(\bar{w}, \bar{t}) - \mu^{cap}(\bar{w}, \bar{t})|$. In the case of (8) one may exploit (3), (4) and once more the upper semicontinuity of μ^{emp} in order to derive that:

$$\begin{aligned}
\Delta &= \lim_{k \rightarrow \infty} (\mu^{cap}(w_k, t_k) - \mu^{emp}(w_k, t_k)) \\
&= \lim_{k \rightarrow \infty} (1 - \mu^{emp}(w_k, t_k) - (1 - \mu^{cap}(w_k, t_k))) \\
&= \limsup_{k \rightarrow \infty} (1 - \mu^{emp}(w_k, t_k) - (1 - \mu^{cap}(w_k, t_k))) \\
&\leq \limsup_{k \rightarrow \infty} (\mu^{emp}(-w_k, -t_k) - (1 - \mu^{cap}(w_k, t_k))) \\
&\leq \mu^{emp}(-\bar{w}, -\bar{t}) - (1 - \mu^{cap}(\bar{w}, \bar{t})) = \mu^{emp}(-\bar{w}, -\bar{t}) - \mu^{cap}(-\bar{w}, -\bar{t}) \\
&\leq |\mu^{emp}(-\bar{w}, -\bar{t}) - \mu^{cap}(-\bar{w}, -\bar{t})| \leq \Delta.
\end{aligned}$$

Hence, $\Delta = |\mu^{emp}(-\bar{w}, -\bar{t}) - \mu^{cap}(-\bar{w}, -\bar{t})|$. Altogether, the assertion follows with $(w^*, t^*) := (\bar{w}, \bar{t})$ in the first case and $(w^*, t^*) := (-\bar{w}, -\bar{t})$ in the second one. \square

We may strengthen the previous Proposition in the sense that not only there exists some cap realizing the discrepancy but that it also has to contain at least one sample point on its relative boundary:

Proposition 2. *For (w^*, t^*) realizing the discrepancy in Proposition 1 it holds that there is some $i \in \{1, \dots, N\}$ such that $\langle w^*, x^i \rangle = t^*$.*

Proof. Assume that $\langle w^*, x^j \rangle \neq t^*$ for all $j \in \{1, \dots, N\}$. Then,

$$\mu^{emp}(w^*, t) = \mu^{emp}(w^*, t^*) \quad (9)$$

for t close to t^* . If $|t^*| < 1$, then one may strictly increase ($t > t^*$) or decrease ($t < t^*$) $\mu^{cap}(w^*, t)$, so that by virtue of (9) the local discrepancy $\Delta(w^*, t)$ can be strictly increased in comparison with the maximal one $\Delta(w^*, t^*) = \Delta$. This is a contradiction. If $t^* = 1$, then

$$\begin{aligned}
\langle w^*, x^j \rangle &< 1 \quad \forall j \in \{1, \dots, N\}, \\
\mu^{cap}(w^*, t^*) &= \mu^{emp}(w^*, t^*) = 0.
\end{aligned}$$

Since $\mu^{cap}(w^*, t)$ is strictly increased for $t < t^* = 1$ while $\mu^{emp}(w^*, t) = 0$ for t close to t^* (see (9)), one may strictly increase the local discrepancy again, so that the same contradiction results. The case $t^* = -1$ follows analogously. \square

An interesting consequence of the previous Proposition is that a cap realizing the discrepancy has always empirical measure not smaller than cap measure:

Corollary 1. *For (w^*, t^*) realizing the discrepancy in Proposition 1 it holds that $\mu^{emp}(w^*, t^*) \geq \mu^{cap}(w^*, t^*)$.*

Proof. Suppose to the contrary, that $\mu^{emp}(w^*, t^*) < \mu^{cap}(w^*, t^*)$. Then, using (3) and (4), we arrive at the contradiction

$$\begin{aligned}
\Delta &= \mu^{cap}(w^*, t^*) - \mu^{emp}(w^*, t^*) \\
&= 1 - \mu^{cap}(-w^*, -t^*) - \\
&\quad (1 + N^{-1} \#\{i | x^i \in H(w^*, t^*) \cap H(-w^*, -t^*)\}) - \mu^{emp}(-w^*, -t^*) \\
&< \mu^{emp}(-w^*, -t^*) - \mu^{cap}(-w^*, -t^*) \leq \Delta.
\end{aligned}$$

Here, the strict inequality follows from the fact that $H(w^*, t^*) \cap H(-w^*, -t^*)$ contains at least one sample point by Proposition 2. \square

Lemma 2. Let $\{x^1, \dots, x^k\} \subseteq \mathbb{S}^{n-1}$ for some $k \in \mathbb{N}$ and let

$$S := \{(w, t) \mid \langle w, x^i \rangle = t \ (i = 1, \dots, k)\} \quad (10)$$

Let

$$p := \text{rank} \left\{ \begin{pmatrix} x^i \\ -1 \end{pmatrix} \right\}_{i=1, \dots, k}.$$

Then, assuming without loss of generality that

$$\text{rank} \left\{ \begin{pmatrix} x^i \\ -1 \end{pmatrix} \right\}_{i=1, \dots, p} = p$$

(i.e., the first p points x^i are affinely independent), the set S defined in (10) has a reduced representation

$$S = \{(w, t) \mid \langle w, x^i \rangle = t \ (i = 1, \dots, p)\}. \quad (11)$$

Proof. By $p \leq k$ it is sufficient to show that the right-hand side of (11) is contained in S as defined in (10). It is therefore enough to show the implication

$$\langle w, x^j \rangle = t \ (j = 1, \dots, p) \implies \langle w, x^i \rangle = t \ (i = p+1, \dots, k). \quad (12)$$

By definition of p , the vectors $\begin{pmatrix} x^i \\ -1 \end{pmatrix}$ ($i = p+1, \dots, k$) are linear combinations of the vectors $\begin{pmatrix} x^j \\ -1 \end{pmatrix}$ ($j = 1, \dots, p$). Hence, for an arbitrarily fixed $i \in \{p+1, \dots, k\}$ there exists some $\lambda \in \mathbb{R}^p$ such that

$$\begin{pmatrix} x^i \\ -1 \end{pmatrix} = \sum_{j=1}^p \lambda_j \begin{pmatrix} x^j \\ -1 \end{pmatrix}.$$

Along with the assumption in (12), both components of this last identity yield that

$$\langle w, x^i \rangle = \sum_{j=1}^p \lambda_j \langle w, x^j \rangle = t \sum_{j=1}^p \lambda_j = t$$

which is the conclusion of (12). □

The proof of Proposition 2 might suggest the idea that a discrepancy realizing cap has to contain not just one but a maximum possible number of sample points on its relative boundary. This intuition is wrong as can be seen from Figure 1. Here, any of the two caps in the left picture contains three points on its relative boundary but realizes a strictly smaller local discrepancy $\Delta(w, t)$ than the small cap in the right picture which contains just two of the three sample points on its relative boundary. As a consequence, the evaluation of the discrepancy Δ cannot be based just on a simple enumeration of local discrepancies $\Delta(w, t)$ associated with affinely independent subsets of the sample points. One has also to consider smaller subsets of sample points for which the hyperplane associated with the cap is not yet fixed. In order to get rid of the remaining degree of freedom, one has to maximize the local discrepancy conditionally to this small subset belonging to the relative boundary of the cap. In the right picture of Figure 1, among all caps having x^2, x^3 on its boundary, the one defined by a vertical hyperplane turned out to maximize the local discrepancy. The crucial argument in order to incorporate this maximization aspect, is provided in the following result:

Lemma 3. Let $\{x^1, \dots, x^k\} \subseteq \mathbb{S}^{n-1}$ be such that

$$\text{rank} \left\{ \begin{pmatrix} x^i \\ -1 \end{pmatrix} \right\}_{i=1, \dots, k} = k.$$

Denote by X_* the matrix whose columns are generated by x^i for $i = 1, \dots, k$ and define

$$\tilde{X}_* := \begin{pmatrix} X_* \\ -\mathbf{1}^T \end{pmatrix}; \quad \gamma := \mathbf{1}^T \left(\tilde{X}_*^T \tilde{X}_* \right)^{-1} \mathbf{1}; \quad \mathbf{1} := (1, \dots, 1)^T.$$

Let (w^*, t^*) be a local solution of the optimization problem

$$\max_{w, t} \{ t \mid \langle w, x^i \rangle = t \ (i = 1, \dots, k), \langle w, w \rangle = 1 \}. \quad (13)$$

Then, it holds that $0 < \gamma \leq 1$. If $\gamma < 1$, then

$$t^* \in \left\{ \pm \left(\frac{1 - \gamma}{\gamma} \right)^{1/2} \right\}, \quad w^* = \frac{1 + (t^*)^2}{t^*} X_* \left(\tilde{X}_*^T \tilde{X}_* \right)^{-1} \mathbf{1}.$$

Moreover, $\gamma = 1$ is equivalent to $t^* = 0$ and we then have $\text{rank } X_* = k - 1$.

Proof. In order to identify (w^*, t^*) via necessary optimality conditions we have first to check if the gradients

$$\left\{ \begin{pmatrix} x^1 \\ -1 \end{pmatrix}, \dots, \begin{pmatrix} x^k \\ -1 \end{pmatrix}, \begin{pmatrix} 2w \\ 0 \end{pmatrix} \right\}$$

with respect to (w, t) of the equality constraints in (13) are linearly independent. We assume a linear combination

$$\begin{pmatrix} 0 \\ 0 \end{pmatrix} = \sum_{i=1}^k \lambda_i \begin{pmatrix} x^i \\ -1 \end{pmatrix} + \mu \begin{pmatrix} 2w \\ 0 \end{pmatrix}.$$

Multiplication of the first component with w yields - taking into account the equality constraints in (13) and comparing the second component - that

$$0 = \sum_{i=1}^k \lambda_i \langle w, x^i \rangle + 2\mu \langle w, w \rangle = t \sum_{i=1}^k \lambda_i + 2\mu = 2\mu.$$

Hence,

$$\sum_{i=1}^k \lambda_i \begin{pmatrix} x^i \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

By assumption of the Lemma, the vectors $\left\{ \begin{pmatrix} x^i \\ -1 \end{pmatrix} \right\}_{i=1, \dots, k}$ are linearly independent, whence $\lambda_i = 0$ for $i = 1, \dots, k$. Furthermore, $\mu = 0$, which altogether proves the linear independence of the gradients of equality constraints in (13).

This allows us to derive the following necessary optimality condition for a local solution (w^*, t^*) of problem (13). Here the gradient of the objective function t appears on the left-hand side:

$$\exists \lambda_1, \dots, \lambda_k, \mu \in \mathbb{R} : \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \sum_{i=1}^k \lambda_i \begin{pmatrix} x^i \\ -1 \end{pmatrix} + \mu \begin{pmatrix} 2w^* \\ 0 \end{pmatrix}. \quad (14)$$

The second component implies that $\sum_{i=1}^k \lambda_i = -1$. Multiplication of the first component by w^* and exploiting the equality constraints in (13) yields that

$$0 = \sum_{i=1}^k \lambda_i \langle w^*, x^i \rangle + 2\mu \langle w^*, w^* \rangle = t^* \sum_{i=1}^k \lambda_i + 2\mu,$$

in particular, $t^* = 2\mu$. With $\lambda := (\lambda_1, \dots, \lambda_k)^T$, the equation in (14) reads as

$$\begin{pmatrix} 0 \\ 1 \end{pmatrix} = \tilde{X}_* \lambda + t^* \begin{pmatrix} w^* \\ 0 \end{pmatrix}. \quad (15)$$

Multiplication of both sides from the left by \tilde{X}_*^T and using the first feasibility constraint $X_*^T w^* = t^* \mathbf{1}$ in (13) results in

$$-\mathbf{1} = \tilde{X}_*^T \tilde{X}_* \lambda + t^{*2} \mathbf{1}.$$

By the assumption of this Lemma, the matrix $\tilde{X}_*^T \tilde{X}_*$ is regular and we can solve the last equation for λ :

$$\lambda = -(1 + t^{*2}) \left(\tilde{X}_*^T \tilde{X}_* \right)^{-1} \mathbf{1}. \quad (16)$$

Recalling that $\mathbf{1}^T \lambda = -1$ we arrive at

$$(1 + t^{*2}) \mathbf{1}^T \left(\tilde{X}_*^T \tilde{X}_* \right)^{-1} \mathbf{1} = 1. \quad (17)$$

By definition of γ , the latter equation implies that we necessarily have $0 < \gamma \leq 1$, and $\gamma = 1$ if and only if $t^* = 0$. In the case $\gamma = 1$ we have that $w^* \in \text{Ker } X_*^T \cap \mathbb{S}^{n-1}$ by feasibility of w^* in (13). Moreover, from (15) we see that $X_* \lambda = 0$ for some $\lambda \neq 0$ which then implies that $\text{rank } X_* = k - 1$ due to

$$k - 1 = \text{rank } \tilde{X}_* - 1 \leq \text{rank } X_* = k - \dim \text{Ker } X_* \leq k - 1.$$

If, in contrast, $0 < \gamma < 1$, then, by (17),

$$t^* = \pm \left(\frac{1 - \gamma}{\gamma} \right)^{1/2}. \quad (18)$$

The first component of (15) reads

$$0 = X_* \lambda + t^* w^*.$$

Using the representation (16) for λ we obtain that

$$w^* = \frac{1 + t^{*2}}{t^*} X_* \left(\tilde{X}_*^T \tilde{X}_* \right)^{-1} \mathbf{1}$$

which completes the proof. \square

Note, the fact that (w^*, t^*) is a local maximum in (13) does not imply $t^* \geq 0$ in case of $k = n$. We proceed with the following purely technical Lemma which will be needed to cope with a degenerate subcase in our main result later on.

Lemma 4. *Let $\{x^1, \dots, x^N\} \subseteq \mathbb{S}^{n-1}$. For any $I \subseteq \{1, \dots, N\}$ let X_I be the matrix whose columns are $x^i, i \in I$. Define $\tilde{X}_I := \begin{pmatrix} X_I \\ -\mathbf{1}^T \end{pmatrix}$ and let be $\tilde{X} := \tilde{X}_{\{1, \dots, N\}}$. Let $w_0 \in \mathbb{S}^{n-1}$ be given such that*

$$I_0 := \{i \in \{1, \dots, N\} \mid \langle w_0, x^i \rangle = 0\} \neq \emptyset$$

and such that it holds

$$w_0 \in \arg \max_{w \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1}} \mu^{\text{emp}}(w, 0), \quad (19)$$

$$\text{rank } \tilde{X}_{I_0} < \min \{n, \text{rank } \tilde{X}\}, \quad \text{rank } X_{I_0} = \text{rank } \tilde{X}_{I_0} - 1. \quad (20)$$

Then there exist $w_1 \in \mathbb{S}^{n-1}$ and I_1 with $I_0 \subseteq I_1 \subseteq \{1, \dots, N\}$ such that

$$w_1 \in \text{Ker } X_{I_1}^T \cap \mathbb{S}^{n-1}, \quad \mu^{\text{emp}}(w_1, 0) = \mu^{\text{emp}}(w_0, 0), \quad (21)$$

$$\text{rank } X_{I_1} = \text{rank } X_{I_0} + z, \quad \text{rank } \tilde{X}_{I_1} = \text{rank } \tilde{X}_{I_0} + z \quad (22)$$

for some natural number $z \geq 1$.

Proof. We claim that assumptions (19) and (20) imply that the index set

$$J_0 := \{j \in \{1, \dots, N\} \mid \langle w_0, x^j \rangle > 0\}$$

is nonempty. Indeed, in case that $J_0 = \emptyset$, we would have that $\mu^{\text{emp}}(w_0, 0) = N^{-1} \#I_0$ and that $\langle w_0, x^i \rangle \leq 0$ for all $i \in \{1, \dots, N\}$, which amounts to $\mu^{\text{emp}}(-w_0, 0) = 1$. Then, since $-w_0 \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1}$, it would follow that

$$1 = \mu^{\text{emp}}(-w_0, 0) \leq \mu^{\text{emp}}(w_0, 0) = N^{-1} \#I_0 \leq 1.$$

Consequently, $N = \#I_0$, hence $\tilde{X} = \tilde{X}_{I_0}$ and we arrive at the contradiction

$$\text{rank } \tilde{X} = \text{rank } \tilde{X}_{I_0} < \min \{n, \text{rank } \tilde{X}\} \leq \text{rank } \tilde{X}.$$

Therefore, $J_0 \neq \emptyset$.

From the assumption $w_0 \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1}$ and from the definitions of I_0, J_0 we observe that

$$\mu^{\text{emp}}(w_0, 0) = N^{-1} (\#I_0 + \#J_0). \quad (23)$$

In order to show the existence of some suitable w_1 let us consider the following optimization problem:

$$\min_w \{ \varphi(w) \mid w \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1}, \varphi(w) \geq 0 \}, \quad \varphi(w) := \min_{j \in J_0} \langle w, x^j \rangle. \quad (24)$$

Observe that the feasible set of this problem is nonempty (it contains w_0) and compact by continuity of φ . Hence, once more by continuity of φ , the problem admits a solution w_1 . Select $j_1 \in J_0$ satisfying $\langle w_1, x^{j_1} \rangle = \varphi(w_1)$ and put $K := I_0 \cup \{j_1\}$.

Next, we prove that $\varphi(w_1) = 0$. Assume to the contrary that $\varphi(w_1) > 0$. Because $x^{j_1} \notin \text{span } \{x^i\}_{i \in I_0}$ by $w_1 \in \text{Ker } X_{I_0}^T$ and $\langle w_1, x^{j_1} \rangle > 0$, we observe that

$$\text{rank } X_K = \text{rank } X_{I_0} + 1. \quad (25)$$

Assumption (20) and property (25) imply that

$$\dim \text{Ker } X_K^T = n - \text{rank } X_K = n - \text{rank } X_{I_0} - 1 > 0,$$

whence $\text{Ker } X_K^T \cap \mathbb{S}^{n-1} \neq \emptyset$. Select some $\bar{w} \in \text{Ker } X_K^T \cap \mathbb{S}^{n-1}$ moreover satisfying $\langle w_1, \bar{w} \rangle \geq 0$ and define

$$\bar{w}_t := t\bar{w} + (1-t)w_1 \quad \forall t \in [0, 1].$$

Then, with $\|\cdot\|$ referring to the Euclidean norm, we derive that

$$\|\bar{w}_t\| > 1 - t > 0 \quad \forall t \in (0, 1). \quad (26)$$

In particular, recalling that $w_1 \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1}$ is a solution of (24) and that

$$\bar{w} \in \text{Ker } X_K^T \cap \mathbb{S}^{n-1} \subseteq \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1},$$

we may define

$$\tilde{w}_t := \bar{w}_t / \|\bar{w}_t\| \in \text{Ker } X_{I_0}^T \cap \mathbb{S}^{n-1} \quad \forall t \in (0, 1).$$

Now, since $\lim_{t \downarrow 0} \|\bar{w}_t\| = \|w_1\| = 1$, we infer that for all $j \in J_0$,

$$\lim_{t \downarrow 0} \langle \tilde{w}_t, x^j \rangle = \lim_{t \downarrow 0} (t \langle \bar{w}, x^j \rangle + (1-t) \langle w_1, x^j \rangle) / \|\bar{w}_t\| = \langle w_1, x^j \rangle \geq \varphi(w_1) > 0.$$

Consequently, $\varphi(\tilde{w}_t) \geq 0$ for small enough $t > 0$ which entails that \tilde{w}_t is feasible in problem (24) for small enough $t > 0$. On the other hand, since $\bar{w} \in \text{Ker } X_K^T$, we may exploit the relation $\langle \bar{w}, x^{j_1} \rangle = 0$, in order to derive from (26) and $\varphi(w_1) > 0$ that

$$\begin{aligned} \varphi(\tilde{w}_t) &\leq \langle \tilde{w}_t, x^{j_1} \rangle = (t \langle \bar{w}, x^{j_1} \rangle + (1-t) \langle w_1, x^{j_1} \rangle) / \|\bar{w}_t\| \\ &= (1-t) \varphi(w_1) / \|\bar{w}_t\| < \varphi(w_1) \end{aligned}$$

for all $t \in (0, 1)$, whence the contradiction that for small enough $t > 0$ \tilde{w}_t is feasible in problem (24) and realizes a strictly smaller objective value than the solution w_1 . Hence, we have shown that $\varphi(w_1) = 0$.

From $\langle w_1, x^{j_1} \rangle = 0$ it follows that $w_1 \in \text{Ker } X_K^T \cap \mathbb{S}^{n-1}$. Put

$$I_1 := \{i \in \{1, \dots, N\} \mid \langle w_1, x^i \rangle = 0\}$$

and obtain that

$$I_0 \subset K \subseteq I_1. \quad (27)$$

Since $\text{Ker } X_K^T \subseteq \text{Ker } X_{I_0}^T$, the relation

$$\langle w_1, x^j \rangle \geq \varphi(w_1) = 0 \quad \forall j \in J_0$$

implies together with equation (23) and assumption (19) that

$$\mu^{emp}(w_1, 0) \geq N^{-1} (\#I_0 + \#J_0) = \mu^{emp}(w_0, 0) \geq \mu^{emp}(w_1, 0).$$

Hence, $\mu^{emp}(w_1, 0) = \mu^{emp}(w_0, 0)$. This, along with the definition of I_1 shows the two relations claimed in (21).

In order to verify (22), let finally $I_1 \setminus I_0 = \{k_1, \dots, k_s\}$ and put $K_0 := I_0$, $K_\ell := I_0 \cup \{k_1, \dots, k_\ell\}$ for $\ell = 1, \dots, s$. Obviously,

$$\text{rank } \tilde{X}_{K_\ell} - \text{rank } \tilde{X}_{K_{\ell-1}} \geq \text{rank } X_{K_\ell} - \text{rank } X_{K_{\ell-1}}$$

for all $\ell = 1, \dots, s$, whence

$$\text{rank } \tilde{X}_{I_1} - \text{rank } \tilde{X}_{I_0} \geq \text{rank } X_{I_1} - \text{rank } X_{I_0} =: z. \quad (28)$$

By (25) and (27), we have that $z \geq 1$. On the other hand, assumption (20) implies that

$$\begin{aligned} \text{rank } \tilde{X}_{I_1} - \text{rank } \tilde{X}_{I_0} &\leq \text{rank } X_{I_1} + 1 - \text{rank } \tilde{X}_{I_0} \\ &= z + \text{rank } X_{I_0} + 1 - (\text{rank } X_{I_0} + 1) = z. \end{aligned} \quad (29)$$

Estimations (28) and (29) show the relations claimed in (22) and we are done. \square

We finish this section by a simple implication which will be needed several times in the proof of the main result below and which uses the notation introduced in Lemma 4:

$$\begin{aligned} \text{Ker } X_I^T \cap \mathbb{S}^{n-1} \neq \emptyset &\implies \dim \text{Ker } X_I^T \geq 1 \\ &\implies \text{rank } \tilde{X}_I \leq \text{rank } X_I + 1 \leq n \\ &\implies \text{rank } \tilde{X}_I \leq \min\{n, \text{rank } \tilde{X}\}. \end{aligned} \quad (30)$$

3 Main Result

After the preparations of the previous section, we are in a position to derive a formula allowing for the computation of the cap discrepancy Δ of any sample on the sphere by enumeration of finitely many easy to calculate local discrepancies $\Delta(w, t)$. The Theorem divides into a simpler part for the case that the half space realizing the discrepancy does not contain the origin on its boundary (i.e., $t^* \neq 0$ for the couple (w^*, t^*) in Proposition 1) and a technically more delicate part in case that the origin does belong to that boundary (i.e., $t^* = 0$).

Theorem 1. *Let $\{x^1, \dots, x^N\} \subseteq \mathbb{S}^{n-1}$. For any $I \subseteq \{1, \dots, N\}$ with $I \neq \emptyset$, let X_I be the matrix whose columns are x^i ($i \in I$) and define $\tilde{X}_I := \begin{pmatrix} X_I \\ -\mathbf{1}^T \end{pmatrix}$ as well as $\tilde{X} := \tilde{X}_{\{1, \dots, N\}}$. Consider the following finite families of index sets:*

$$\begin{aligned} \Phi_1 &:= \left\{ I \subseteq \{1, \dots, N\} \mid 1 \leq \text{rank } \tilde{X}_I = \#I \leq \min\{n, \text{rank } \tilde{X}\}; \gamma_I < 1 \right\}, \\ \Phi_0 &:= \left\{ I \subseteq \{1, \dots, N\} \mid 1 \leq \text{rank } \tilde{X}_I = \#I = \min\{n, \text{rank } \tilde{X}\}; \gamma_I = 1 \right\}, \end{aligned}$$

where $\gamma_I := \mathbf{1}^T \left(\tilde{X}_I^T \tilde{X}_I \right)^{-1} \mathbf{1}$. For $I \in \Phi_1 \cup \Phi_0$ put

$$t_I := \begin{cases} \left(\frac{1-\gamma_I}{\gamma_I} \right)^{1/2} & I \in \Phi_1 \\ 0 & I \in \Phi_0 \end{cases}, \quad w_I := \begin{cases} \frac{1+t_I^2}{t_I} X_I \left(\tilde{X}_I^T \tilde{X}_I \right)^{-1} \mathbf{1} & I \in \Phi_1 \\ \in \text{Ker } X_I^T \cap \mathbb{S}^{n-1} & I \in \Phi_0 \end{cases},$$

where the selection of w_I in case of $I \in \Phi_0$ is arbitrary. Then, for the cap discrepancy it holds that $\Delta = \max\{\Delta_1, \Delta_0\}$, where

$$\begin{aligned} \Delta_1 &:= \begin{cases} \max_{I \in \Phi_1} \max \{ \Delta(w_I, t_I), \Delta(-w_I, -t_I) \} & \text{if } \Phi_1 \neq \emptyset \\ 0 & \text{else} \end{cases}, \\ \Delta_0 &:= \begin{cases} \max_{I \in \Phi_0} \max \{ \Delta(w_I, 0), \Delta(-w_I, 0) \} & \text{if } \Phi_0 \neq \emptyset \\ 0 & \text{else} \end{cases}. \end{aligned}$$

Proof. Let $(w^*, t^*) \in \mathbb{S}^{n-1} \times [-1, 1]$ be such that (see Prop. 1)

$$\Delta = \Delta(w^*, t^*) = |\mu^{emp}(w^*, t^*) - \mu^{cap}(w^*, t^*)|.$$

Since, by Corollary 1

$$\mu^{emp}(w^*, t^*) \geq \mu^{cap}(w^*, t^*) \quad (31)$$

it follows that

$$\Delta = \mu^{emp}(w^*, t^*) - \mu^{cap}(w^*, t^*). \quad (32)$$

We define the (disjoint) index sets

$$I^* := \{i \in \{1, \dots, N\} \mid \langle w^*, x^i \rangle = t^*\}, \quad J^* := \{i \in \{1, \dots, N\} \mid \langle w^*, x^i \rangle > t^*\}.$$

From Proposition 2, we infer that $I^* \neq \emptyset$. Let

$$S := \left\{ (w, t) \in \mathbb{S}^{n-1} \times [-1, 1] \left| \begin{array}{ll} \langle w, x^i \rangle = t & i \in I^* \\ \langle w, x^i \rangle > t & i \in J^* \\ \langle w, x^i \rangle < t & i \in \{1, \dots, N\} \setminus (I^* \cup J^*) \end{array} \right. \right\}.$$

The definitions of Δ and (w^*, t^*) imply along with (31) that

$$(w^*, t^*) \in \arg \max_{(w, t) \in \mathbb{S}^{n-1} \times [-1, 1]} \mu^{emp}(w, t) - \mu^{cap}(w, t). \quad (33)$$

Since $(w^*, t^*) \in S$ it follows that even

$$(w^*, t^*) \in \arg \max_{(w, t) \in S} \mu^{emp}(w, t) - \mu^{cap}(w, t).$$

We observe that $\mu^{emp}(w, t) = N^{-1}(\#I^* + \#J^*) = \text{const}$ for all $(w, t) \in S$. Hence,

$$(w^*, t^*) \in \arg \min_{(w, t) \in S} \mu^{cap}(w, t).$$

Because, $\mu^{cap}(w, t)$ depends on t only and is monotonically decreasing with t (see(2)), (w^*, t^*) is a solution of the optimization problem

$$\max_{w, t} \left\{ t \left| \begin{array}{ll} \langle w, x^i \rangle = t & i \in I^* \\ \langle w, x^i \rangle > t & i \in J^* \\ \langle w, x^i \rangle < t & i \in \{1, \dots, N\} \setminus (I^* \cup J^*) \\ \langle w, w \rangle = 1 \end{array} \right. \right\}.$$

Note, that the constraint $t \in [-1, 1]$ is implicitly contained in the equality constraints above. Next, choose a subset $\bar{I}^* \subseteq I^*$ such that

$$\#\bar{I}^* = \text{rank } \tilde{X}_{\bar{I}^*} = \text{rank } \tilde{X}_{I^*} \quad (34)$$

(using the notation introduced in the statement of the Theorem). By Lemma 2, the optimization problem above can be reformulated as

$$\max_{w, t} \left\{ t \left| \begin{array}{ll} \langle w, x^i \rangle = t & i \in \bar{I}^* \\ \langle w, x^i \rangle > t & i \in J^* \\ \langle w, x^i \rangle < t & i \in \{1, \dots, N\} \setminus (I^* \cup J^*) \\ \langle w, w \rangle = 1 \end{array} \right. \right\}. \quad (35)$$

Since $\langle w^*, x^i \rangle > t^*$ for $i \in J^*$ and $\langle w^*, x^i \rangle < t^*$ for $i \in \{1, \dots, N\} \setminus (I^* \cup J^*)$ and (w^*, t^*) is a solution of the optimization problem (35), it follows that (w^*, t^*) must be a local solution of the optimization problem

$$\max_{w, t} \{ t \mid \langle w, x^i \rangle = t \quad (i \in \bar{I}^*); \langle w, w \rangle = 1 \}. \quad (36)$$

By (34), this problem satisfies the assumption of Lemma 3 with $X_* := X_{\bar{I}^*}$ and $k := \#\bar{I}^*$. According to that Lemma we have that $0 < \gamma_{\bar{I}^*} \leq 1$ with γ_I as introduced in the statement of this Theorem.

In the case of $\gamma_{\bar{I}^*} < 1$ it follows from Lemma 3 (last statement), that $t^* \neq 0$. Then, by feasibility of (w^*, t^*) in (36), we have that

$$(t^*)^{-1} \tilde{X}_{\bar{I}^*}^T w^* = \mathbf{1} \quad (= (1, \dots, 1) \in \mathbb{R}^{\#\bar{I}^*}).$$

Consequently, $-\mathbf{1} \in \text{range } X_{\bar{I}^*}^T$, and thus,

$$\text{rank } \tilde{X}_{\bar{I}^*} = \text{rank} \begin{pmatrix} X_{\bar{I}^*} \\ -\mathbf{1}^T \end{pmatrix} = \text{rank} (X_{\bar{I}^*}^T \mid -\mathbf{1}) = \text{rank } X_{\bar{I}^*}^T \leq n.$$

Since also $\text{rank } \tilde{X}_{\bar{I}^*} \leq \text{rank } \tilde{X}$, we have shown that $\bar{I}^* \in \Phi_1$. Therefore, with the definitions of t_I, w_I in the statement of this Theorem, we infer from Lemma 3 that $(w^*, t^*) \in \{(w_{\bar{I}^*}, t_{\bar{I}^*}), (-w_{\bar{I}^*}, -t_{\bar{I}^*})\}$. Thus,

$$\Delta = \Delta(w^*, t^*) \leq \max \{\Delta(w_{\bar{I}^*}, t_{\bar{I}^*}), \Delta(-w_{\bar{I}^*}, -t_{\bar{I}^*})\} \leq \Delta_1 \quad (37)$$

with Δ_1 as introduced in the statement of this Theorem.

The remaining part of this proof is devoted to the case $\gamma_{\bar{I}^*} = 1$. From Lemma 3 we observe that $t^* = 0$, and, $\text{rank } X_{\bar{I}^*} = \#\bar{I}^* - 1$. The second equality in (34) along with $\bar{I}^* \subseteq I^*$ yields that $\text{rank } X_{I^*} = \text{rank } X_{\bar{I}^*}$. Hence, the first equality in (34) provides the relation

$$\text{rank } X_{I^*} = \text{rank } \tilde{X}_{I^*} - 1. \quad (38)$$

Moreover, by definition of I^* , one has that $w^* \in \text{Ker } X_{I^*}^T \cap \mathbb{S}^{n-1}$, so that

$$w^* \in \arg \max_{w \in \text{Ker } X_{I^*}^T \cap \mathbb{S}^{n-1}} \mu^{\text{emp}}(w, 0) - \mu^{\text{cap}}(w, 0) = \arg \max_{w \in \text{Ker } X_{I^*}^T \cap \mathbb{S}^{n-1}} \mu^{\text{emp}}(w, 0) - \frac{1}{2} \quad (39)$$

as a consequence of (33). Therefore,

$$w^* \in A := \arg \max_{w \in \text{Ker } X_{I^*}^T \cap \mathbb{S}^{n-1}} \mu^{\text{emp}}(w, 0). \quad (40)$$

Since $\mu^{\text{emp}}(w^*, 0) \geq \frac{1}{2}$, it holds that

$$\mu^{\text{emp}}(w, 0) \geq \frac{1}{2} \quad \forall w \in A. \quad (41)$$

By (30), $w^* \in \text{Ker } X_{\bar{I}^*}^T \cap \mathbb{S}^{n-1}$ implies that $\text{rank } \tilde{X}_{\bar{I}^*} \leq \min \{n, \text{rank } \tilde{X}\}$. We claim the existence of some index set \hat{I} and of some vector \hat{w} such that

$$\begin{aligned} I^* \subseteq \hat{I} \subseteq \{1, \dots, N\}, \quad \text{rank } \tilde{X}_{\hat{I}} &= \min \{n, \text{rank } \tilde{X}\}, \\ \hat{w} \in \text{Ker } X_{\hat{I}}^T \cap \mathbb{S}^{n-1}, \quad \mu^{\text{emp}}(\hat{w}, 0) &= \mu^{\text{emp}}(w^*, 0). \end{aligned} \quad (42)$$

If $\text{rank } \tilde{X}_{\bar{I}^*} = \min \{n, \text{rank } \tilde{X}\}$, then we may choose $\hat{I} := \bar{I}^*$ and $\hat{w} := w^*$ in (42). Otherwise, $\text{rank } \tilde{X}_{\bar{I}^*} < \min \{n, \text{rank } \tilde{X}\}$ and we make use of Lemma 4 starting with the data $I_0 := \bar{I}^*$ and $w_0 := w^*$. Observe that by virtue of (38) and (40), I_0 and w_0 satisfy the assumptions (19) and (20) of that Lemma. Accordingly, we derive the existence of some index set $I_1 \supseteq I_0$ and w_1 satisfying the relations (21) and (22). In particular, $\text{Ker } X_{I_1}^T \subseteq \text{Ker } X_{I_0}^T$, whence both relations in (21) yield that

$$w_1 \in \arg \max_{w \in \text{Ker } X_{I_1}^T \cap \mathbb{S}^{n-1}} \mu^{\text{emp}}(w, 0).$$

Moreover, we infer from (20) and (22) that $\text{rank } X_{I_1} = \text{rank } \tilde{X}_{I_1} - 1$ and from the first relation in (21) and (30) that $\text{rank } \tilde{X}_{I_1} \leq \min \{n, \text{rank } \tilde{X}\}$.

Now, if $\text{rank } \tilde{X}_{I_1} = \min \{n, \text{rank } \tilde{X}\}$, then we may choose $\hat{I} := I_1$ and $\hat{w} := w_1$ in (42) due to (21) and $w_0 = w^*$. Otherwise, $\text{rank } \tilde{X}_{I_1} < \min \{n, \text{rank } \tilde{X}\}$ and so the assumptions (19) and (20) of Lemma 4 are also satisfied for I_1 and w_1 instead of I_0 and w_0 . This allows us to apply Lemma 4 again. In this way, a sequence of index sets I_k and of points w_k ($k = 1, 2, \dots$) is obtained for which $I^* = I_0 \subseteq I_k$ and by (21) and (22)

$$w_k \in \text{Ker } X_{I_k}^T \cap \mathbb{S}^{n-1}, \quad \mu^{\text{emp}}(w_k, 0) = \mu^{\text{emp}}(w_0, 0), \quad \text{rank } \tilde{X}_{I_k} = \text{rank } \tilde{X}_{I_{k-1}} + z_k,$$

where $z_k \in \mathbb{N}$ and $z_k \geq 1$. Since $\text{rank } \tilde{X}_{I_k} \leq \min \{n, \text{rank } \tilde{X}\}$ by (30), the last relation implies that, after finitely many steps, we arrive at the situation $\text{rank } \tilde{X}_{I_k} = \min \{n, \text{rank } \tilde{X}\}$, so that we may define $\hat{I} := I_k$ and $\hat{w} := w_k$ in (42). This finishes the proof of (42).

Next, from (32) and (42) we know that

$$\Delta = \mu^{\text{emp}}(w^*, 0) - \frac{1}{2} = \mu^{\text{emp}}(\hat{w}, 0) - \frac{1}{2}. \quad (43)$$

This relation shows that $(\hat{w}, 0)$ realizes the discrepancy Δ as much as $(w^*, 0)$. Therefore, we may assume that (w^*, t^*) is $(\hat{w}, 0)$ in the beginning of our proof until (36). In particular, analogously to the index set I^* introduced there, we define

$$I_* := \{i \in \{1, \dots, N\} \mid \langle \hat{w}, x^i \rangle = 0\}$$

Following the previous arguments from (34) to (36), we may find an index set $\bar{I}_* \subseteq I_*$ such that

$$\#\bar{I}_* = \text{rank } \tilde{X}_{\bar{I}_*} = \text{rank } \tilde{X}_{I_*}. \quad (44)$$

In particular,

$$\hat{w} \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}. \quad (45)$$

Moreover, $(\hat{w}, 0)$ is a local solution of the optimization problem

$$\max_{w, t} \{t \mid \langle w, x^i \rangle = t \quad (i \in \bar{I}_*); \langle w, w \rangle = 1\}. \quad (46)$$

By (44), this problem satisfies the assumption of Lemma 3 with $X_* := X_{\bar{I}_*}$ and $k := \#\bar{I}_*$. According to that Lemma (last statement) we have that $\gamma_{\bar{I}_*} = 1$ with γ_I as introduced in the statement of this Theorem. Applying (30) to $\hat{w} \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}$, we observe that

$$\text{rank } \tilde{X}_{\bar{I}_*} \leq \min \{n, \text{rank } \tilde{X}\}.$$

On the other hand, since $\hat{I} \subseteq I_*$ by (42) and by definition of I_* , the rank relation in (42) leads to

$$\text{rank } \tilde{X}_{I_*} \geq \text{rank } \tilde{X}_{\hat{I}} = \min \{n, \text{rank } \tilde{X}\},$$

whence, along with (44)

$$\#\bar{I}_* = \text{rank } \tilde{X}_{\bar{I}_*} = \min \{n, \text{rank } \tilde{X}\}. \quad (47)$$

Summarizing, we have shown that $\bar{I}_* \in \Phi_0$.

If in (47) $\text{rank } \tilde{X}_{\bar{I}_*} = \text{rank } \tilde{X}$, then there exist coefficients λ_j^i such that

$$\begin{pmatrix} x^i \\ -1 \end{pmatrix} = \sum_{j \in \bar{I}_*} \lambda_j^i \begin{pmatrix} x^j \\ -1 \end{pmatrix} \quad \forall i = 1, \dots, N.$$

Therefore, we have for all $i = 1, \dots, N$ and all $w \in \text{Ker } X_{\bar{I}_*}^T$ that

$$\langle x^i, w \rangle = \left\langle \begin{pmatrix} x^i \\ -1 \end{pmatrix}, \begin{pmatrix} w \\ 0 \end{pmatrix} \right\rangle = \sum_{j \in \bar{I}_*} \lambda_j^i \left\langle \begin{pmatrix} x^j \\ -1 \end{pmatrix}, \begin{pmatrix} w \\ 0 \end{pmatrix} \right\rangle = \sum_{j \in \bar{I}_*} \lambda_j^i \langle x^j, w \rangle = 0.$$

This amounts to saying that $\mu^{emp}(w, 0) = 1$ for all these w and, so,

$$\Delta(w, 0) = |\mu^{emp}(w, 0) - \mu^{cap}(w, 0)| = 1/2 \quad \forall w \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}.$$

We conclude from (45) and (43) that

$$\Delta = \left| \mu^{emp}(\hat{w}, 0) - \frac{1}{2} \right| = \Delta(\hat{w}, 0) = 1/2 = \Delta(w, 0) \quad \forall w \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}.$$

Therefore, the value of $\Delta(w_{\bar{I}_*}, 0)$ in the definition of Δ_0 (see statement of this Theorem) does not depend on the choice of $w_{\bar{I}_*} \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}$. It follows from $\bar{I}_* \in \Phi_0$ that $\Delta \leq \Delta_0$.

Otherwise, if in (47) $\text{rank } \tilde{X}_{\bar{I}_*} = n$, then $\dim \text{Ker } \tilde{X}_{\bar{I}_*}^T = 1$ and so there exists some $(\tilde{w}, \tilde{t}) \in \mathbb{S}^n$ with $\text{Ker } \tilde{X}_{\bar{I}_*}^T = \text{span}\{(\tilde{w}, \tilde{t})\}$. Let $w \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}$ be arbitrary. Then, $(w, 0) \in \text{Ker } \tilde{X}_{\bar{I}_*}^T$ and, hence, there is some $\lambda \in \mathbb{R}$ with $(w, 0) = \lambda(\tilde{w}, \tilde{t})$. Clearly, $\lambda \neq 0$ by $w \in \mathbb{S}^{n-1}$. It follows that $\tilde{t} = 0$, whence $\tilde{w} \in \mathbb{S}^{n-1}$ and $|\lambda| = 1$. Therefore, $w = \pm \tilde{w}$. Thus, we have shown that $w \in \{\tilde{w}, -\tilde{w}\}$ for all $w \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}$. On the other hand, $\hat{w} \in \{\tilde{w}, -\tilde{w}\}$ by (45). Therefore,

$$\begin{aligned} \Delta &= \left| \mu^{emp}(\hat{w}, 0) - \frac{1}{2} \right| = \Delta(\hat{w}, 0) \leq \max \{ \Delta(\tilde{w}, 0), \Delta(-\tilde{w}, 0) \} \\ &= \max \{ \Delta(w, 0), \Delta(-w, 0) \} \quad \forall w \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}. \end{aligned}$$

As in the previous case, the value of $\Delta(w_{\bar{I}_*}, 0)$ in the definition of Δ_0 does not depend on the choice of $w_{\bar{I}_*} \in \text{Ker } X_{\bar{I}_*}^T \cap \mathbb{S}^{n-1}$. Again, $\bar{I}_* \in \Phi_0$ implies that $\Delta \leq \Delta_0$.

Summarizing, our proof has shown by case distinction that necessarily $\Delta \leq \Delta_1$ (see (37)) or $\Delta \leq \Delta_0$. Therefore, $\Delta \leq \max\{\Delta_1, \Delta_0\}$. On the other hand, each of the quantities Δ_1, Δ_0 is either zero or corresponds to a concrete value $\Delta(w, t)$ for some $w \in \mathbb{S}^{n-1}$ and $t \in [-1, 1]$. Hence, in any case $\max\{\Delta_1, \Delta_0\} \leq \Delta$. This finishes the proof. \square

We want to conclude this section with some algorithmic remarks. The formula provided by the main theorem is appropriate for easy implementation. To compute the cap discrepancy for a given point set one has to consider all possible selections $I \subseteq \{1, \dots, N\}$ with cardinality less than or equal to $\min\{n, \text{rank } \tilde{X}\}$ and one has to check whether the selection is included in one of the two sets Φ_1 or Φ_0 . This check implies first a verification of $\text{rank } \tilde{X}_I$, and secondly, if applicable, the computation of $\gamma_I = \mathbf{1}^T \left(\tilde{X}_I^T \tilde{X}_I \right)^{-1} \mathbf{1}$. For these selected I one has to compute the local discrepancy by the given formulas. Finally, the discrepancy is found as the maximum of the considered local discrepancies. A Matlab implementation of the enumeration formula for the spherical cap discrepancy provided by the Theorem is accessible through the link:

<https://www.wias-berlin.de/people/heitsch/capdiscrepancy>

We observe that the cardinality of index sets to be checked in the proven formula is at most

$$\sum_{i=1}^{\min\{n, \text{rank } \tilde{X}\}} \binom{N}{i}.$$

Whether calculating the spherical cap discrepancy is NP-hard (or W[1]-hard) is left open for future work. Clearly, this aspect of complexity limits the application of the formula to low-dimensional spheres and moderate sample sizes. Hence, it will not be suitable for verifying asymptotic aspects of sampling schemes. On the other hand, it may be used to correctly calibrate the efficiency of sampling schemes within a certain range of the sample size.

4 Numerical Illustration

In this section we illustrate the application of the derived formula for the spherical cap discrepancy to spheres \mathbb{S}^2 to \mathbb{S}^5 with sample sizes reaching from 2000 to 100 depending on dimension. Samples were generated by normalizations of Monte Carlo simulated independent Gaussian distributions which are approximations of the uniform distribution on the sphere. For the sake of comparison, we oppose the results to the application of an easily computable lower estimate of the discrepancy as it was used, e.g., in [1]: Given a sample $\{x^1, \dots, x^N\}$, we clearly have that

$$\tilde{\Delta} := \max_{i=1, \dots, N} \sup_{t \in [-1, 1]} |\mu^{emp}(x^i, t) - \mu^{cap}(x^i, t)| \leq \Delta.$$

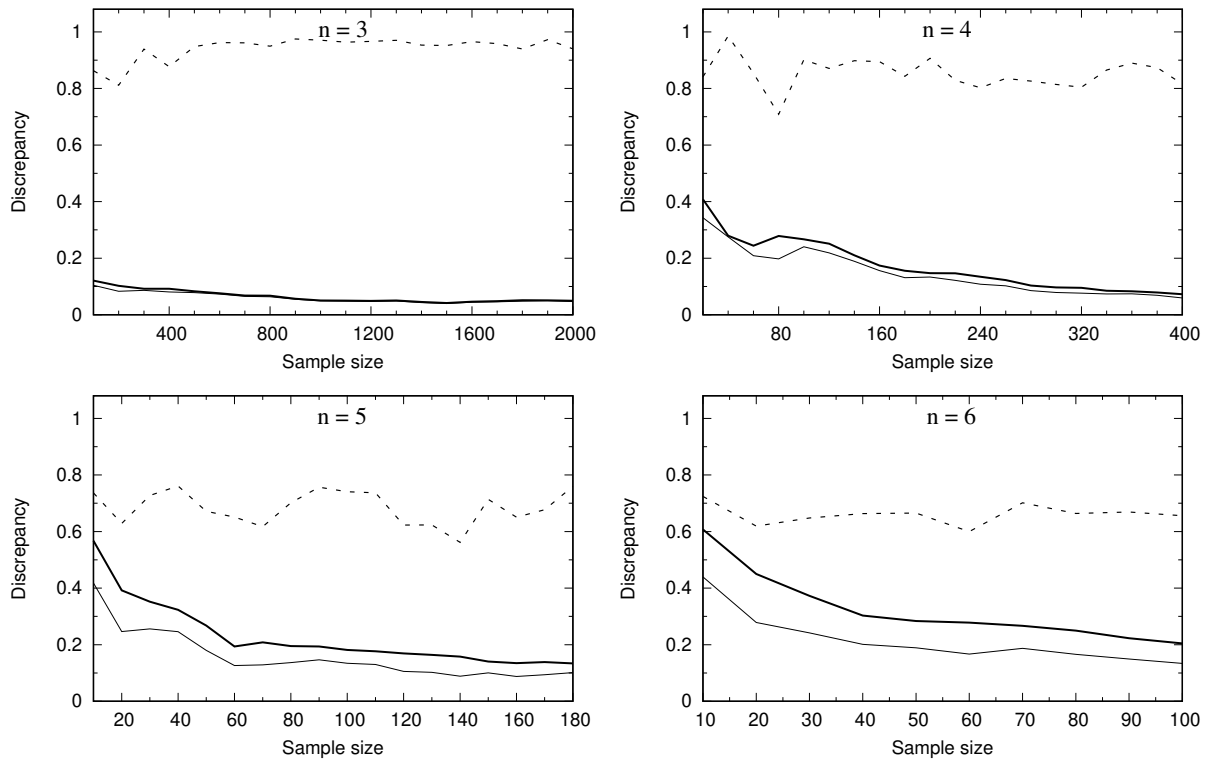

Figure 3: Plot of discrepancy Δ (thick line), of its lower estimate $\tilde{\Delta}$ (thin line) and of the ratio $\tilde{\Delta}/\Delta$ (dashed line) for different dimensions ($n = 3, 4, 5, 6$) and sample sizes.

Fig. 3 shows the numerical results. We observe the following trends:

- Both, Δ and $\tilde{\Delta}$ are decreasing with increasing sample size.
- The absolute difference between Δ and $\tilde{\Delta}$ decreases with the sample size.
- The absolute difference between Δ and $\tilde{\Delta}$ increases with the dimension of the sphere.
- The ratio between $\tilde{\Delta}$ and Δ is basically constant for variable sample size in each dimension of the sphere (with different values of the constant).
- The constant itself is decreasing with the dimension of the sphere.

In particular, it seems that the discrepancy can be replaced by its lower estimate without loss of information in \mathbb{S}^2 starting from a sample size of approximately 500. For larger dimension or sample size, it appears that at least the decay rate with respect to the sample size is well reflected by the lower estimate (approximately constant ratio with the true discrepancy), while the deviation from the true discrepancy becomes significant.

N	10	20	40	100	180	400	1000	2000
\mathbb{S}^2	0	0	0	3	30	499	15924	252313
\mathbb{S}^3	0	0	2	139	1911	77449	-	-
\mathbb{S}^4	0	0	14	1932	48134	-	-	-
\mathbb{S}^5	0	1	92	32658	-	-	-	-

Table 1: CPU time (in seconds) of the enumeration formula for selected instances.

All computations are performed on a standard computer with single CPU (3.2 GHz). Table 1 displays the CPU time for selected instances of the tested range of N and n .

In order to illustrate even more directly the application of the proven formula, we provide a comparison of 4 sampling schemes on \mathbb{S}^2 for small sample sizes (≤ 1000). The first two methods are based on the already mentioned fact that the normalization to unit length of a standard Gaussian distribution $\mathcal{N}(0_m, I_m)$ yields a uniform distribution on \mathbb{S}^{m-1} . Therefore, we may simulate the Gaussian distribution via Monte Carlo (MC) or via Quasi-Monte Carlo (QMC). As an alternative, we follow the proposal in [1], to use the equal-area Lambert transform from the unit square to \mathbb{S}^2 , again for MC and QMC. For QMC, we applied in both cases Sobol' sequences as a special case of low-discrepancy sequences.

Figure 4: Discrepancy as a function of sample size for 4 different sampling schemes in original form (left) and Log-Log Plot (right). For details see text.

Figure 4 (left) shows the corresponding plots of the discrepancy as a function of the sample size (20 steps with an increment of sample size by 50 points at a time). Not surprisingly, the QMC-based samples clearly outperform their MC counterparts. Moreover, in both classes, the Lambert transformation yields slightly better results than the normalization of Gaussians. The Log-Log plot (right) incorporates two gray strips with slopes identical to $-1/2$ (upper strip) and $-3/4$ (lower strip) with empirically shifted intercepts. It can be seen that the MC-based methods are closely tied with the expected decay rate of $-1/2$, whereas the QMC counterparts get a slope slightly above the optimal rate of $-3/4$.
