Abstract

In this paper we continue the researches of hypothesis testing problems leading to infinitely divisible distributions which have been started in the papers by Ingster, 1996a, 1997.

Let the $n$-dimensional Gaussian random vector $x = \xi + v$ is observed where $\xi$ is a standard $n$-dimensional Gaussian vector and $v \in R_n$ is an unknown mean. We consider the minimax hypothesis testing problem $H_0 : v = 0$ versus alternatives $H_1 : v \in V_n$, where $V_n$ is $l_p^q$-ball of radius $R_{1,n}$ with $l_p^n$-balls of radius $R_{2,n}$ removed. We are interesting in the asymptotics (as $n \to \infty$) of the minimax second kind error probability $\beta_n(\alpha) = \beta_n(\alpha; p, q, R_{1,n}, R_{2,n})$ where $\alpha \in (0, 1)$ is a level of the first kind error probability. Close minimax estimation problem had been studied by Donoho and Johnstone (1994).

We show that the asymptotically least favorably priors in the problem of interest are of the product type: $\pi^n = \pi_n \times \cdots \times \pi_n$. Here $\pi_n = (1 - h_n)\delta_0 + \frac{h_n}{2}(\delta_{-b_n} + \delta_{b-n})$ are the three-point measures with some $h_n = h_n(p, q, R_{1,n}, R_{2,n}$ and $b_n = b_n(p, q, R_{1,n}, R_{2,n})$. This reduces the problem of interest to Bayesian hypothesis testing problems where the asymptotics of error probabilities had been studied by Ingster, 1996a, 1997.

In particularly, if $p \leq q$, then the asymptotics of $\beta_n(\alpha)$ are of Gaussian type, but if $p > q$ then its are either Gaussian or degenerate or belong to a special class of infinitely divisible distributions which was described in Ingster, 1996a, 1997.
1 Introduction

1.1 Setting

Let $n$-dimensional Gaussian random vector $x = \xi + v$ is observed where $\xi$ is a standard $n$-dimensional Gaussian vector with zero mean and unit covariance matrix and $v \in R_n$ is an unknown mean. We test null hypothesis $H_0 : v = 0$ versus the alternative $H_1 : v \in V_n$, here $V_n$ is $l_q^n$-ball of radius $R_{1,n}$ with $l_p^n$-balls of radius $R_{2,n}$ removed:

$$V_n = V_n^{p,q}(R_{1,n}, R_{2,n}) = \{v = (v_1, \ldots, v_n) \in R^n : \sum_{i=1}^n |v_i|^p \geq R_{1,n}^p, \sum_{i=1}^n |v_i|^q \leq R_{1,n}^q\}$$

where $p \in (0, \infty), q \in (0, \infty]$ are given values and $R_{1,n} > 0, R_{2,n} > 0$ are given sequences of radiiuses (with evident modifications for $q = \infty$ or $p = \infty$; we consider the case $p < \infty$ in this paper). We assume

$$R_{1,n} \leq R_{2,n} \quad \text{for} \quad p > q; \quad R_{1,n}n^{-1/p} \leq R_{2,n}n^{-1/q} \quad \text{for} \quad p \leq q$$

which imply that the sets $V_n$ are nonempty.

We deal with asymptotically minimax hypothesis testing problem (see Ingster, 1993). Let $\Psi_{n,\alpha}$ be the set of tests of level $\alpha$, $\alpha \in (0, 1)$ (the set of measurable functions $\psi : R^n \rightarrow [0, 1]$) such that $\alpha(\psi) \leq \alpha$ where $\alpha(\psi) = E_n, v\psi$ is the first kind error probability. Here and below $E_{n, v}$ means the expectation with respect to Gaussian measure $P_{n, v}$ with the mean $v$ and unit covariance matrix.

Let $\beta_n(\psi, v) = E_n, v(1 - \psi)$ be the second kind error probability and let

$$\beta_n(\psi, V_n) = \sup_{v \in V_n} \beta_n(\psi, v)$$

be the maximum value of the second kind error probability for test $\psi$. Let

$$\beta_n(\alpha) = \beta_n(\alpha, V_n) = \inf_{\psi \in \Psi_{n,\alpha}} \beta_n(\psi, V_n)$$

be the minimax second kind error probability. It is clear that following inequalities hold:

$$0 \leq \beta_n(\alpha) \leq 1 - \alpha.$$

We are interested in the dependence of the asymptotics of $\beta_n(\alpha)$ on $p, q$ and on the behavior of $R_{1,n}$ and $R_{2,n}$ as $n \rightarrow \infty$ for any $\alpha \in (0, 1)$ and in the structure of asymptotically minimax tests $\psi_{n,\alpha}$ such that

$$\alpha_n(\psi_{n,\alpha}) \leq \alpha + o(1), \quad \beta_n(\psi_{n,\alpha}) \leq \beta_n(\alpha, V_n) + o(1).$$

Here and below the asymptotic relations are understood as $n \rightarrow \infty$. 

1
1.2 Discussion

The problem under consideration seems to be the most natural minimax hypothesis testing problem of increasing dimension. Analogous minimax estimation problem has been studied by Donoho and Johnstone (1994).

Close infinite dimensional problems of hypothesis testing were considered by Ermakov (1990), by Ingster (1990, 1993, 1996b) and by Suslina (1993, 1996). It was assumed that infinite dimensional Gaussian vector \( x = \xi + v \) is observed where \( v \in l_2 \) and \( \xi \) is a sequence of independent standard Gaussian variables. Alternatives \( H_1 : v \in V \) correspond to a family of subsets \( V \in l_2 \) with asymptotic parameter \( \epsilon \to 0 \).

These papers deal with alternatives of the form \( l_q \)-ellipsoids with \( l_p \)-balls removed:

$$ V_c = \{ v \in l_2 : \sum_{i=1}^{\infty} |v_i|^p \geq (\rho_p / \epsilon)^p, \sum_{i=1}^{\infty} |v_i / a_i|^q \leq \epsilon^{-q} \}. \quad (1.4) $$

Here \( \{a_i\} \) is a given sequence of semi-exes of \( l_q \)-ellipsoid for fixed orthonormal basis in \( L_2 \) which corresponds to the problem of detection of a signal in Gaussian white noise; the factor \( \epsilon > 0 \) in (1.4) corresponds to normalization.

It is clear that the problem under consideration in this paper is the same as in \((1.4)\) for "series scheme" with \( \rho_p / \epsilon = R_{1,n} \) and \( a_i / \epsilon = R_{2,n} \) for \( i = 1, \ldots, n, a_i = 0 \) for \( i > n \) and we can try to use methods of Ingster (1996b) and Suslina (1996) to this problem.

These methods are used for \( p < \infty \) and reduce the considerable problem to the extreme problem:

$$ u_c^2 = \inf \{ || \pi ||^2 : \pi \in \Pi_c \} \quad (1.5) $$

where \( \Pi_c \) is the set of sequences \( \pi = (\pi_1, \ldots, \pi_n, \ldots) \) of probability measures \( \pi_i \) on the real line such that

$$ \sum_{i=1}^{\infty} E_{\pi_i} |u|^p \geq (\rho_p / \epsilon)^p, \sum_{i=1}^{\infty} E_{\pi_i} |u / a_i|^q \leq \epsilon^{-q} $$

and

$$ || \pi ||^2 = \sum_{i=1}^{\infty} || \pi_i ||^2 = \sum_{i=1}^{\infty} \int_{R^1} \int_{R^1} (e^{uv} - 1) \pi_i(du) \pi_i(dv). $$

Under some assumptions (they are formulated in terms of the sequence \( \pi_c = (\pi_{c,1}, \ldots, \pi_{c,n}, \ldots) \) which minimizes \((1.3)\)) it is shown in Ingster (1996b) that analogous to \((1.3)\) values \( \beta_c(\alpha) \) satisfy to the relation

$$ \beta_c(\alpha) = \beta_c(\alpha, P_{\pi^*}) + o(1) = \Phi(t_\alpha - u_\epsilon) + o(1), \epsilon \to 0. \quad (1.6) $$

Here \( \beta_c(\alpha, P_{\pi^*}) \) is minimum second kind error probability of tests of the level \( \alpha \) for simple Bayesian alternative which corresponds to a mixture

$$ P_{\pi^*} = \int P_{\pi^*}(dv) = \prod_{i=1}^{\infty} \int_{R^1} P_{\pi_{c,i}}(dv) $$
over product-measure $\pi^e = \pi_{e_1} \times \cdots \times \pi_{e_i} \times \cdots$ and $u_i$ is defined by (1.5). Here and below $\Phi$ stands for distribution function of standard Gaussian low and $t_\alpha$ for this $(1 - \alpha)$-quantile.

The relation (1.6) is based on the asymptotical normality of the log-likelihood ratio $\log (dP_{\pi^e} / dP_0)$

The extreme problem (1.5) may be separated in ”one-dimensional” problem

$$f_{p,q}(\lambda, \nu) = \inf \{ \| \pi \|_2: E_\pi |u|^p \geq \lambda^p, \quad E_\pi |u|^q \leq \nu^q \}, \quad (1.7)$$

and in ”two-sequence” problem

$$u^2 = \inf \{ \sum_{i=1}^\infty f_{p,q}(\lambda_i, \nu_i): \sum_{i=1}^\infty \lambda^p_i = (\rho / \epsilon)^p, \quad \sum_{i=1}^\infty \nu^q_i = \epsilon^{-p} \} \quad (1.8)$$

(or ”one-sequence” problem if $p = q$).

These problems had been studied by Ingster, 1990, 1993 (the case $p = q$) and by Suslina, 1996 (the case $p \neq q$ and the power sequence of semi-axes $a_n \asymp n^{-t}, t > 0$).

In particular, it was shown that the solution of one-dimensional problem (1.7) is the symmetrical three-point measure

$$\pi(b, h) = (1 - h)\delta_0 + \frac{h}{2} (\delta_b + \delta_{-b}) \quad (1.9)$$

for some $b = b(p, q, \lambda, \nu) > 0, h = h(p, q, \lambda, \nu) \in (0, 1]$; here $\delta_b$ is Dirac mass at the point $b \in R^1$.

More exactly, if $\lambda < \nu$ and $p \leq q$, then the set under constraints is empty. If $\lambda \geq \nu$ or $p > q$, then there are the three possible equalities:

(i) \quad $h = 1, \quad b = \lambda$;

(ii) \quad $h = (\lambda / b_p)^p, \quad b = b_p$ (for $p > 2$);

(iii) \quad $hb^p = \lambda^p, \quad hb^q = \nu^q$.

Here the value $b_p > 0$ for $p > 2$ is the root of the equation $p \tanh b^2 / 2 = b^2$; this value minimizes the function $b^p \sinh (b^2 / 2)$.

Note that these relations imply equality in the first inequality (1.7). However if the relation (iii) does not hold, then it is not possible the equality in the second inequality in (1.7 and this inequality is not essential in the problem).

The relations between $p, q, \lambda, \nu$ and equalities (i), (ii) and (iii) are described by following

Lemma 1.1 (Suslina, 1996)

1. Let $p \leq 2$ and $p \leq q$. Then the relation (i) holds.

2. Let $p \leq 2$ and $p > q$. Then the relation (i) holds, if $\lambda < \nu$ and the relation (iii) holds, if $\lambda \geq \nu$.

3. Let $\infty > p > 2$ and $p \leq q$. Then the relation (i) holds, if $\lambda > b_p$; the relation (ii) holds, if $\lambda \leq b_p \leq (\nu^q / \lambda^p)^{1/(q-p)}$ for $p < q$ or $\lambda \leq b_p$ for $p = q$; the relation (iii) holds, if $\lambda \leq b_p, \quad p < q, \quad (\nu^q / \lambda^p)^{1/(q-p)} \leq b_p$. 

3
4. Let $\infty > p > 2$ and $p > q$. Then the relation (i) holds, if $b_p < \lambda < \nu$; the relation (ii) holds, if $\lambda \geq \nu$ and $(\lambda/b_p)^p \leq (\nu/b_p)^q$ or $\nu > \lambda$ and $\lambda < b_p$; the relation (iii) holds, if $\lambda \geq \nu$ and $(\lambda/b_p)^p > (\nu/b_p)^q$.

These results imply that

$$f_{p,q}(\lambda, \nu) = 2h^2 \sinh^2(b^2/2)$$

where $b = b(p, q, \lambda, \nu)$ and $h = h(p, q, \lambda, \nu)$ are described in Lemma 1 and if $p \leq q$, then $b_n = O(1)$ for any sequences $\lambda_n$ and $\nu_n$ such that $f_{p,q}(\lambda_n, \nu_n) = O(1)$ as $n \to \infty$.

The required to (1.6) assumptions may be formulated in terms of extreme sequences $b_\epsilon = b_{\epsilon,i}$ and $h_\epsilon = h_{\epsilon,i}$ and they are checked for a power sequence of semi-exes: $a_n \approx n^{-t}$ as $n \to \infty$, $t > 0$. In particular, one of sufficient conditions is that $\sup \epsilon b_{\epsilon,i} = O(1)$ as $\epsilon \to \infty$ and it is fulfilled for $p \leq q$ if $u_\epsilon = O(1)$.

If we use these methods to the problem under consideration, then we obtain the problem

$$u_n^2 = \inf \{ \sum_{i=1}^{n} f_{p,q}(\lambda_i, \nu_i) : \sum_{i=1}^{n} \lambda_i^p = R_{1,n}^p, \sum_{i=1}^{n} \nu_i^q = R_{2,n}^q \},$$

which is analogous to (1.8). One can easily see that, by the symmetry,

$$u_n^2 = n f_{p,q}(\lambda_n, \nu_n) = 2nh_n^2 \sinh^2(b_n^2/2) \tag{1.10}$$

where

$$\lambda_n = R_{1,n}/n^{1/p}, \quad \nu_n = R_{2,n}/n^{1/q}, \quad b_n = b(p, q, \lambda_n, \nu_n), \quad h_n = h(p, q, \lambda_n, \nu_n).$$

If $b_n = O(1)$ here, then the assumptions of Ingster (1996b) hold and we obtain the relation which is analogous to (1.6):

$$\beta_n(\alpha) = \beta_n(\alpha, P_{\alpha}) + o(1) = \Phi(t_n - u_n) + o(1), \quad n \to \infty. \tag{1.11}$$

Here $u_n$ is defined in (1.10) and $\pi^n$ is the product measure:

$$\pi^n = \pi^\alpha(b_n, h_n) = \prod_{i=1}^{n} \pi_{n,i}, \quad \pi_{n,i} = \pi_n(\alpha, b_n, h_n) \tag{1.12}$$

where $\pi(b_n, h_n)$ are defined by (1.9).

In particularly, the relation (1.11) holds, if $p \leq q$. In fact, if $u_n = O(1)$, then one can easily check, that $b_n = O(1)$. If $b_n \to \infty$, then, by making $R_{1,n}$ smaller, one can reduce the consideration to the case of arbitrarily large $b_n = O(1)$ and $u_n = O(1)$ which implies $\beta_n(\alpha) \to 0$. However if $\infty > p > q$, then it is possible that $b_n \to \infty$ and $u_n = O(1)$.

The goal of this paper is to study this case. We can use the results by Ingster (1996b) in this case also, if $b_n = o(\sqrt{\log n})$. However, if $b_n \sim \sqrt{\log n}$, then, as we show below, the asymptotics (1.11) may not hold. If $nh_n \to \infty$, then the product
priors (1.12) are the asymptotically least favorable also, however, as it follows from Ingster, 1996a, 1997, the asymptotics of distributions of the log-likelihood ratios \( \log \left( \frac{dP_\pi}{dP_0n} \right) \) are not Gaussian, but degenerate or infinite divisible of the special type. Note that analogous asymptotically least favorable product priors (1.12) arise in Donoho and Johnstone (1994) for minimax estimation problem also.

The main considerations later assume \( \infty > p > q, \ b_n \to \infty \) which by Lemma 1.1 correspond to

\[ nh_n b_n^p = R_{n,1}^p, \ nh_n b_n^q = R_{n,2}^q \]  

or

\[ b_n = \left( \frac{R_{1,n}^p}{R_{2,n}^q} \right) \left( p-q \right), \ nh_n = \left( \frac{R_{2,n}^q}{R_{1,n}^p} \right) \left( p-q \right). \]

In fact, as it was noted above, the case \( p < q \leq \infty \) can be considered by the methods of Ingster, 1993, 1996b and Suslina, 1996 and corresponds to the Gaussian case. The case \( \infty = p \geq q \) can be considered by the methods of Ingster, 1993, nn. 4.4, 5.4 and corresponds to degenerate case with \( b_n = R_{1,n}, \ nh_n = 1 \) (see the Theorem 3 later).

In the next section we remind the results in Bayesian problem and formulate the analogous results for the problem under consideration. In sections 3 - 8 we give the proofs.

## 2 Main results

Remind the results of Ingster, 1997 on the distributions of the log-likelihood ratios for the product priors (1.12)

\[ l_n = l_n(b_n, h_n) = \log \left( \frac{dP_\pi}{dP_0n} \right) = \sum_{i=1}^{n} \log(1 + h_n \xi(x_i, b_n)) \]  

where

\[ \xi(x, b) = \exp(-b^2/2) \cosh bx - 1 \]

and on the asymptotics of the values \( \beta_n(\alpha, P_\pi) \) in Bayesian problem.

If \( b_n \to \infty \) and \( h_n \to 0 \), then define two sequences \( T_n \) and \( \tau_n \). Let \( T_n \) is defined by the relation

\[ nh_n \xi(T_n, b_n) = 1 + o(1). \]

One can easily see that

\[ T_n = \frac{b_n}{2} + \frac{\log 2h_n^{-1}}{b_n} + o(1). \]

Put

\[ \tau_n = \frac{T_n}{b_n} = \frac{1}{2} + \frac{\log h_n^{-1}}{b_n^2} + o(1) \]

and assume without loss of generality that

\[ \tau_n \to \tau \in [1/2, \infty]. \]
Also if \( b_n = O(1) \) or \( h_n \sim 1 \), then put \( \tau = \infty \).

It was shown in Ingster, 1996a, 1997, that there are three different types of the limit distributions of the log-likelihood statistics (2.14) and three types of the asymptotics of the second kind error probabilities \( \beta_n(\alpha, P_{x^n}) \) which correspond to the three intervals of \( \tau: \tau \in [2, \infty) \) (Gaussian type), \( \tau \in (1, 2) \) (infinite-divisible type) and \( \tau \in (1/2, 1] \) (degenerate type).

### 2.1 Gaussian case: \( \tau \in [2, \infty) \)

Put \( u_n = +\sqrt{u_n^2} \) where

\[
 u_n^2 = \begin{cases} 
 2nh_n^2(\sinh(b_n^2/2))^2, & \text{if } \tau \in (2, \infty], \\
 \frac{1}{2}nh_n^2e^{b_n^2} \Phi(T_n - 2b_n), & \text{if } \tau = 2.
\end{cases}
\]

Then (Ingster, 1997, Theorem 1)

\[
 \beta_n(\alpha, P_{x^n}) = \Phi(t_\alpha - u_n) + o(1)
\]

and if \( u_n \sim 1 \), then the log-likelihood statistics \( l_n \) in (2.14) are asymptotically Gaussian \( N(-u_n^2/2, u_n^2/2) \) under the null hypothesis \( H_0 \) and \( N(u_n^2/2, u_n^2/2) \) under the Bayesian alternative \( H_{n,x^n} \).

In considerable problem we have

**Theorem 1** Let \( \tau \geq 2 \). Then

1. **Lower bounds:**

   \[
   \beta_n(\alpha, V_n) \geq \Phi(t_\alpha - u_n) + o(1).
   \]

2. **Upper bounds.** Let us consider the sequences of the tests

   \[
   \psi_{n,\alpha} = 1_{\{t_n > T_{n,\alpha} \} \cup \{\max_i |x_i| > H_n\}}.
   \]

Here \( H_n \) is some sequence such that \( n\Phi(H_n) \to 0 \), \( T_{n,\alpha} = t_\alpha u_n - u_n^2/2 \). If \( \tau > 3 \), then \( \tilde{t}_n = t_n \) and if \( \tau \leq 3 \), then \( \tilde{t}_n = l_n(\tilde{b}_n, \tilde{h}_n) \) where the values \( \tilde{b}_n, \tilde{h}_n \) correspond to \( p, q, R_{n,2} \) and changed \( R_{n,1} = R_{n,1}(1 - b_n^3) \). Then \( \alpha(\psi_{n,\alpha}) = \alpha + o(1) \);

\[
 \beta_n(\psi_{n,\alpha}, V_n) \leq \Phi(t_\alpha - u_n) + o(1).
\]

It means that the sequence of the tests \( \psi_{n,\alpha} \) is asymptotically minimax.

**Corollary 2.1**

1. Let \( p \leq q \). Then

   \[
   \beta_n(\alpha, V_n) = \Phi(t_\alpha - u_n) + o(1).
   \]

2. Let \( p \leq q, p \leq 2 \). Then

   \[
   \beta_n(\alpha, V_n) = \beta_n(\psi_{n,\alpha}, V_n) + o(1) = \Phi(t_\alpha - \tilde{u}_n) + o(1).
   \]

Here \( \tilde{u}_n^2 = nb_n^4/2 \) and \( \psi_{n,\alpha} = 1_{\{\tilde{t}_n > t_\alpha\}} \) where \( \tilde{t}_n = (2n)^{-1/2} \sum_{i=1}^n (x_i^2 - 1) \) is the sequence of \( c \)-square tests.

It means that there is the unit family of tests which is asymptotically minimax for any \( p \leq q, p \leq 2, R_{n,1}, R_{n,2} \).
Proof of the Corollary. By making \( R_{n,1} \) smaller, we can assume that \( u_n = O(1) \).
The statement n.1 follows from the boundness \( h_n \) in the case \( p \leq q \) by the Lemma 1.1. If \( p \leq 2 \) also, then \( h_n = 1 \). Note that \( u_n \sim \tilde{u}_n \) in this case and the statement n.2 follows from Ingster, 1993, n. 5.2.

### 2.2 Infinitely divisible case: \( \tau \in (1,2) \)

Put \( c_n = 2n\Phi(-T_n) \) and assume without loss of generality that \( c_n \to c \in [0, \infty] \).

For \( \tau \in (1,2) \) and \( c \in (0, \infty) \) let us define two independent infinitely divisible random variables \( \zeta^0 = \zeta^0_{c,\tau} \) and \( \zeta^\Delta = \zeta^\Delta_{c,\tau} \) with the characteristic functions

\[
\log \varphi^0(z) = iz\gamma^0 + \int_{-\infty}^{\infty} (e^{izt} - 1 - \frac{izt}{1 + t^2})dL^0(t),
\]

\[
\log \varphi^\Delta(z) = \int_{-\infty}^{\infty} (e^{izt} - 1)dL^\Delta(t).
\]

Here \( L^0 = L^0_{c,\tau} \) and \( L^\Delta = L^\Delta_{c,\tau} \) are the Levi spectral functions (see Petrov, 1981) which are zero for \( t < 0 \) and for \( t > 0 \)

\[
L^0(t) = -c(e^t - 1)^{-\tau},
\]

\[
L^\Delta(t) = -\frac{d}{dt}L^0(t) = -\frac{c}{\tau - 1}(e^t - 1)^{1-\tau}.
\]

The constant \( \gamma^0 \) in (2.19) is defined by the relation

\[
E\zeta^0 = \gamma^0 + \int_0^\infty \frac{t^3}{1 + t^2}dL^0(t) = cI^0(\tau)
\]

where

\[
I^0(\tau) = \int_0^\infty (\log(1 + u^{-1/\tau}) - u^{-1/\tau})du.
\]

This is equivalent to

\[
E\exp \zeta^0 = 1.
\]

Note that for the Levi spectral functions \( L = L^0 \) and \( L = L^\Delta \) one has from (2.21) and (2.22) that

\[
\int_{|x|>1} |x|^p dL(x) < \infty
\]

for any \( p > 0 \) which implies that the random variables \( \zeta^0 \) and \( \zeta^\Delta \) have finite moments of any order. The distributions of \( \zeta^0 \) and \( \zeta^\Delta \) are absolutely continuous. The support of \( \zeta^0 \) is \( R^1 \) but the support of \( \zeta^\Delta \) is the positive halfline \( R^1_+ = \{ t \geq 0 \} \) (see Petrov (1981) for general theorems which imply these properties).

Let \( F^0 = F^0_{c,\tau} \) and \( F^1 = F^1_{c,\tau} \) be the distribution functions of \( \zeta^0 \) and of \( \zeta^1 = \zeta^0 + \zeta^\Delta \) and let \( t^0(\alpha) = t^0_{c,\tau}(\alpha) \) be the \((1-\alpha)\)-quantile of \( \zeta^0 \): \( F^0(t^0(\alpha)) = 1-\alpha \).

Then (Ingster, 1997, Theorem 2) the following relations hold.
1. If \( c = 0 \), then \( \beta_n(\alpha, P_{\pi_n}) \to 1 - \alpha \).
2. If \( c = \infty \), then \( \beta_n(\alpha, P_{\pi_n}) \to 0 \).
3. Let \(c \in (0, \infty)\). Then \(l_n \to \xi^0\) under \(P_{n,0}\) - probability, \(l_n \to \xi^1\) under \(P_{n,\pi}\) - probability and
\[
\beta_n(\alpha, P_{\pi}) \to F^1(\ell^0(\alpha)).
\]

In considerable problem we have

**Theorem 2** Let \(\tau \in (1, 2)\). Then

1. **Lower bounds:**
   \[
   \beta_n(\alpha, V_n) \geq \beta_n(\alpha, P_{\pi}) + o(1).
   \]

2. **Upper Bounds.** Let us consider the sequences of the tests (2.17) where \(H_n\) is some sequence such that \(n \Phi(H_n) \to 0\), \(T_{n,\alpha} = \ell^0_{c,\tau}(\alpha)\) and \(I_n = n(b_n, h_n)\); here the values \(b_n, h_n\) correspond to \(p, q, R_{n,2}\) and to changed \(R_{n,1} = R_{n,1}(1-b_n^3)\). Then \(\alpha(\psi_{n,\alpha}) = \alpha + o(1)\),
   \[
   \beta_n(\psi_{n,\alpha}, V_n) \leq \beta_n(\alpha, P_{\pi}) + o(1).
   \]

It means that the sequence of the tests \(\psi_{n,\alpha}\) is asymptotically minimax.

### 2.3 Degenerate case: \(\tau \in [1/2, 1]\)

Let \(nh_n \to \infty\). Put
\[
\lambda_n = nh_n \Phi(b_n - T_n)
\]
and assume without loss of generality that \(\lambda_n \to \lambda \in [0, \infty]\).

Then (Ingster, 1997, Theorem 3)

1. If \(\lambda = 0\), then \(\beta_n(\alpha, P_{\pi}) \to 1 - \alpha\).
2. If \(\lambda = \infty\), then \(\beta_n(\alpha, P_{\pi}) \to 0\).
3. Let \(\lambda \in (0, \infty)\). Then \(l_n \to -\lambda\) under null hypothesis \(H_0\)
   \[
   \beta_n(\alpha, P_{\pi}) \to (1 - \alpha) \exp(-\lambda).
   \]

For considerable problem we have

**Theorem 3**

1. **Lower bounds.** Let \(\tau = 1\).
   a) Let \(nh_n \to \infty\); also \(nh_n/\log n \to \infty\) or \(nh_n\) is an integer. Then
   \[
   \beta_n(\alpha, V_n) \geq \beta_n(\alpha, P_{\pi}) + o(1) = (1 - \alpha) \exp(-\lambda_n) + o(1).
   \]
   b) Let \(nh_n = O(1)\) and \(nh_n\) is an integer. Then
   \[
   \beta_n(\alpha, V_n) \geq (1 - \alpha)(\Phi(\sqrt{2 \log n - b_n}))^{nh_n} + o(1).
   \]

2. **Upper bounds.** Let us consider the sequences of the tests
\[
\psi_{n,\alpha} = 1\{\max_i \{x_i > H_{n,\alpha}\}\}.
\]
where \(H_{n,\alpha} = \sqrt{2 \log n + o(1)}\) is such sequence that \((1 - 2\Phi(-H_{n,\alpha}))^n = 1 - \alpha\) (this implies \(\alpha(\psi_{n,\alpha}) = \alpha\)).
a) Let \( \tau = 1, \ nh_n \to \infty \). Then

\[
\beta_n(\psi, V_n) \leq \beta_n(\alpha, P_{\sigma_n}) + o(1) = (1 - \alpha) \exp(-\lambda_n) + o(1).
\]

b) Let \( \tau = 1, \ nh_n = O(1) \). Then

\[
\beta_n(\psi, V_n) \leq (1 - \alpha)(\Phi(\sqrt{2\log n - b_n}))^{nh_n} + o(1).
\]

3. Consistent properties. Let one of the following assumptions hold:

(i): \( \tau < 1 \); (ii): \( \tau = 1 \) and \( \lambda_n \to \infty \); (iii): \( \tau \in (1, \infty) \) and \( c_n \to \infty \).

Then for the tests (2.23) one has: \( \beta_n(\psi, V_n) \to 0 \) for any \( \alpha \in (0, 1) \).

Remark 2.1

1. The nn. 1, 2 of the Theorem mean that for \( \tau = 1 \) the tests (2.23) are asymptotically minimax, if \( nh_n / \log n \to \infty \) or \( nh_n \) is an integer.

2. The n. 3 of the Theorem means that for \( \tau < 2 \) the tests (2.23) are asymptotically consistent in minimax sense, if it is possible to construct asymptotically consistent sequence of tests.

3 Proof of the Theorems : lower bounds

To obtain the lower bounds we can assume: if \( \tau \geq 2 \), then \( u_n \propto 1; \) if \( \tau \in (1, 2) \), then \( c_n \propto 1 \). Note that these relations imply \( b_n^2 = O(\log n) \) and \( nh_n / \log n \to \infty \) (see Ingster, 1977). For \( \tau = 1 \) assume \( \lambda_n \propto 1 \) and \( nh_n / \log n \to \infty \) or \( k_n = nh_n \) is an integer. Note that \( b_n^2 = O(\log n) \) also in this case.

For an integer \( k = k_n \) let us consider the sets \( \tilde{V} = V_n, V_n, b_n \):

\[
\tilde{V} = \left\{ v \in \mathbb{R}^n : v = b_n(t_1, \ldots, t_n), t_i \in \{-1, 0, 1\}, i = 1, \ldots, n, \sum_{i=1}^{n} t_i = k_n \right\}.
\]

It is clear that \( \tilde{V} \subset V_n \) for \( k_n = nh_n \) which implies the inequality

\[
\beta_n(\alpha, V_n) \geq \beta_n(\alpha, \tilde{V}_n). \tag{3.24}
\]

It was shown in Ingster, 1977, Theorem 4, that if \( k_n \to \infty \), then

\[
\beta_n(\alpha, \tilde{V}_n) = \beta_n(\alpha, P_{\sigma_n}) + o(1) \tag{3.25}
\]

and if \( k_n = O(1) \), then

\[
\beta_n(\alpha, \tilde{V}_n) = (1 - \alpha)(\Phi(\sqrt{2\log n - b_n}))^{k_n} + o(1)
\]

which imply the lower bounds of the Theorems 1-3 for an integer \( k_n = nh_n \).

Let \( nh_n \) is not integer, \( nh_n / \log n \to \infty \). By making \( R_{2, n} \) smaller: \( R_{2, n}^* = R_{2, n}(1 - \delta_{n, 0}) \), we can get an integer \( k_n = nh_n^*; \) \( nh_n > k_n > nh_n - 1 \) with

\[
h_n^* = h_n(1 - \delta_{n, 1}), \ b_n^* = b_n(1 + \delta_{n, 2}), \ \delta_{n, 0} \times \delta_{n, 1} \times \delta_{n, 2} = O((nh_n)^{-1}) \to 0
\]
which implies the decrease \( \beta_n(\alpha, V_n) \) only.

Analogous to the proof of the Theorem 4 in Ingster, 1997, let us observe the following \textit{asymptotical continuity property} of the values \( \beta_n(\alpha, P_{\pi_n}) \) which follows from Theorems 1 - 3 in this paper.

Let

\[
h_n^* = h_n((1 - \delta_{n,1}), \quad b_n^* = b_n((1 - \delta_{n,2}), \quad \delta_{n,1} = o(1), \quad \delta_{n,2} = o(b_n^{-2}), \quad b_n \to 0.
\]

Then for any \( \alpha \in (0,1) \)

\[
\beta_n(\alpha, P_{\pi_n}(b_n), h_n^*)) = \beta_n(\alpha, P_{\pi_n}(b_n), h_n) + o(1).
\]

Using this continuity property and (3.24), (3.25) one has the lower bounds from the Theorems, if \( b_n^2 = O(nh_n) \). The last relation holds by \( nh_n / \log n \to \infty \). The lower bounds are proved.

4 \textbf{General remarks to the proofs of the upper bounds}

First, note that to prove the upper bounds of the Theorems 1-3 we can assume \( b_n \to \infty \) by the results for \( b_n = O(1) \) follow from Ingster, 1993. Also we can assume that \( u_n \to 1, \quad c_n \to 1, \quad \lambda_n \to 1 \) respectively (see the proof of the Theorem 1 in Ingster, 1997). These imply the relation (1.13).

Also remind some technical relations from Ingster, 1997. In the cases \( b_n \to \infty \) and \( u_n = O(1) \) or \( c_n = O(1) \) or \( \lambda_n = O(1) \) one has

\[
T_n \to \infty, \quad h_n \to 0, \quad h_n \to 2 \exp \left( \frac{b_n^2}{2} - T_nb_n \right). \quad (4.26)
\]

Let us put

\[
z_n(x) = h_n \xi(x, b_n), \quad w_n(x) = \log(1 + z_n(x))
\]

and note that for any \( \delta > 0 \) and \( y = |x| - T_n > \delta \) the following representations hold

\[
z_n(x) = e^{bh_n}(1 + o(1)), \quad w_n(x) = \log(1 + e^{bh_n}(1 + o(1))), \quad \sup_{|x| \leq T_n - \delta} |w_n(x)| \to 0. \quad (4.27)
\]

Here and later we use the well know relations: as \( x \to \infty, \quad \delta = o(x) \)

\[
\Phi(-x) \sim \frac{1}{x \sqrt{2\pi}} e^{-x^2/2}, \quad \Phi(-x + \delta) \sim \Phi(-x) e^{x\delta}. \quad (4.28)
\]

Define the function \( T_n(t) \) by

\[
w_n(T_n(t)) = t, \quad T_n(t) \geq 0. \quad (4.29)
\]

By \( w_n(|x|) \) is increasing in \( |x| \), it follows from (4.27), (2.15) that for any \( t > 0 \)

\[
T_n(t) = T_n + \frac{\log(e^t - 1)}{b_n} + o \left( \frac{1}{b_n} \right), \quad \{x : w_n(x) < t\} = (-T_n(t), T_n(t)). \quad (4.30)
\]
Remind (Ingster, 1997) that under the assumptions $u_n \propto 1$ and $\tau \geq 2$ one has

$$n\Phi(-T_n) \rightarrow 0; \quad b_n^2 \sim \frac{\log n}{2(\tau - 1)} \quad \log n h_n \sim \frac{2\tau - 3}{4(\tau - 1)} \log n;$$

under the assumptions $c_n \propto 1$ and $\tau \in (1, 2)$ one has

$$c_n = 2n\Phi(-T_n) \propto 1; \quad b_n^2 \sim \frac{2\log n}{\tau^2}, \quad \log n h_n \sim (1 - \tau^{-1})^2 \log n;$$

and under the assumptions $\lambda_n \propto 1$ and $\tau = 1$ one has

$$c_n = 2n\Phi(-T_n) = o(\lambda_n) \rightarrow 0; \quad b_n^2 \sim 2\log n, \quad \log n h_n = o(1).$$

Note that by the asymptotical normality of $\tilde{l}_n$ (Ingster, 1997, Theorem 1) and continuity property we have the relations:

$$\alpha + o(1) \leq o(\psi_{n, \alpha}) \leq \begin{cases} \alpha + o(1), & \text{if } n\Phi(H_n) \rightarrow 0, \\ \alpha + 2\delta + o(1), & \text{if } n\Phi(H_n) \leq \delta. \end{cases}$$

By these relations to proof the upper bounds in the Theorems 1, 2 it is enough for any $\delta > 0$ to estimate the second kind error probabilities $\beta_n(\psi_{n, \alpha}, V_n)$ for such tests $\psi_{n, \alpha} = \psi_{n, \alpha, \delta}$ that $n\Phi(H_n) \leq \delta$.

To estimate $\beta_n(\psi_{n, \alpha}, V_n)$ we use the inequality:

$$\beta_n(\psi_{n, \alpha}, v) = P_v(\tilde{l}_n \leq T_{n, \alpha}, \max_i |x_i| \leq H_n) \leq \min\{P_v(\max_i |x_i| \leq H_n), P_v(\tilde{l}_n \leq T_{n, \alpha})\}. \tag{4.34}$$

Let us consider the probabilities $P_v^1 = P_v(\max_i |x_i| \leq H_n)$. Note that for any $\delta > 0$ there is such $B > 0$ that $P_v^1 < \delta$ if any of the following two relations hold:

$$\max_i |v_i| > H_n + B, \quad \sum_i \Phi(|v_i| - H_n) > B. \tag{4.35}$$

In fact,

$$P_v^1 = \prod_i (\Phi(H_n - |v_i|) - \Phi(-H_n - |v_i|)) < \Phi(H_n - \max_i |v_i|) \leq \Phi(-B), \tag{4.36}$$

$$P_v^1 = \prod_i (1 - \Phi(-H_n + |v_i|) - \Phi(-H_n - |v_i|)) <$$

$$< \prod_i (1 - \Phi(-H_n + |v_i|)) < \exp(-\sum_i \Phi(-H_n + |v_i|)) \leq \exp(-B). \tag{4.37}$$

By the relations (4.34) - (4.35) it is enough to estimate the probabilities $P_v(\tilde{l}_n \leq T_{n, \alpha})$ (or the probabilities $P_v(\tilde{l}_n \leq T_{n, \alpha})$ where $\tilde{l}_n = \tilde{l}_n \mathbb{1}_{\{\max_i |x_i| \leq \tilde{l}_n\}}$ is $H_n$-truncated $\tilde{l}_n$) for $v \in V_n \cap V_n^B$ where

$$V_B^n = \{v \in \mathbb{R}^n: \max_i |v_i| \leq B + H_n, \sum_i \Phi(|v_i| - H_n) \leq B\} \tag{4.38}$$
for large enough $B > 0$ and $\hat{H}_n \geq H_n > 0$.

Introduce the values $Q_n$. If $\tau > 2$, then put $Q_n = T_n - b_n + d_n$, if $\tau > 2$, then put $Q_n = T_n / 2$ (this corresponds to $d_n = b_n - T_n / 2$). Here $d_n \to \infty$ is such sequence that $d_n = o(b_n)$ (using (4.26), (4.31) one can check that these relations hold for $\tau = 2$ also). If $\tau \in (1, 2)$, then put $Q_n = \eta b_n$, $\eta \in (1, \tau)$.

Let us consider the sets

$$V_{n,1} = \{ v \in V_n \cap V_\beta^* : \max_i |v_i| \leq Q_n \},$$

$$V_{n,2} = \{ v \in V_n \cap V_\beta^* : \max_i |v_i| > Q_n \}.$$

Choose the values $H_n$. Let $\tau > 3$. Put $H_n = \sqrt{2 \log n}$. By (4.31) one has $Q_n - H_n \to \infty$ which implies $V_{n,2} = \emptyset$ in this case.

Let $\tau \in [2, 3]$. Using (4.31), (4.28) put $H_n = T_n - t_n / b_n$ with such $t_n \to \infty$ that $n\Phi(H_n) \to 0$ and if $\tau > 2$, then $t_n = o(b_n)$ and if $\tau = 2$, then $t_n = o(b_n / d_n)$, $2d_n = 2b_n - T_n$.

Let $\tau \in (1, 2)$. Using (4.32), (4.28) put $H_n = T_n + t(\delta) / b_n$ for such $t(\delta)$ that $n\Phi(H_n) < \delta$.

Denote $m_n(v)$ the number of coordinates $|v_i| > Q_n$.

**Lemma 4.1** *For any* $\tau \in (1, 3)$ *one has*

$$\sup_{v \in V_{n,2}} m_n(v) = o(nh_n / b_n^3).$$

**Proof of the Lemma.** Assume that there is such sequence $v = v^{(n)} \in V_{n,2}$ and $A > 0$ that $m_n(v^{(n)}) > Anh_n b_n^{-3}$.

First, let $\tau \geq 2$. By $H_n < T_n$ using (4.28) one has for large enough $n$ and some constant $B > 0$:

$$\sum_i \Phi(|v_i| - H_n) \geq m_n(v) \Phi(d_n - b_n) \geq Bb_n^{-4} nh_n \exp(-(b_n - d_n)^2 / 2)$$

$$\geq nh_n^2 e^{b_n^2} \Phi(T_n - 2b_n) = 2u_n^2 \times 1$$

by if $T_n - 2b_n > -B$ for any $B < \infty$ (it corresponds to $\tau > 2$), then using (4.26) one has

$$b_n^4 h_n e^{b_n^2} \Phi(T_n - 2b_n) \times b_n^4 h_n \exp(b_n^2 + (b_n - d_n)^2 / 2) \times$$

$$\times b_n^4 \exp(-b_n(d_n - B) - d_n^2 / 2) \to 0$$

and if $T_n - 2b_n = -d_n / 2 \to \infty$, (it corresponds to $\tau = 2$), then

$$b_n^4 h_n e^{b_n^2} \Phi(-d_n / 2) \times b_n^4 d_n^{-1} \exp(-(b_n - d_n) d_n / 2) \to 0.$$

Let $\tau \in (1, 2)$. By $n\Phi(-H_n) \leq \delta$ one has for some $b > 0$:

$$\sum_i \Phi(|v_i| - H_n) \geq bm_n(v) \Phi(\eta b_n - T_n) \times$$

$$\times b_n^4 nh_n \exp(-(T_n - \eta b_n)^2 / 2) \gg nT_n^{-1} e^{-T_n^2 / 2} \times n\Phi(-T_n) \times 1$$
by for \( \eta \in (1, \tau) \)

\[
h_n^{-1} \exp(-T_n^2/2) \asymp \exp(-(T_n - b_n)^2/2) = o(\exp(-(T_n - \eta b_n)^2/2)).
\]

These relations contradict to the assumption \( v = v^{(n)} \in V^n_B \) which proves the Lemma.

Put \( \bar{v} = (\bar{v}_1, ..., \bar{v}_n) \) where \( \bar{v}_i = v_i 1_{\{|v_i| \leq Q_n\}} \). It is clear that \( \bar{v} \in V^n_B \). Also if \( v \in V_{n,2} \), then using (1.13) and the Lemma 4.1 one has for large enough \( n \):

\[
\bar{v} \in \tilde{V}_n = V_n^{p,q}(R_{1,n}, R_{2,n}), \quad \tilde{R}_{1,n} = R_{1,n}(1 - b_n^{-3})
\]

by

\[
\sum_i |\bar{v}_i|^p \geq \sum_i |v_i|^p - m_n(v)(H_n + B)^p \geq R_{1,n}^p - o(n h_n b_n^{-3}) \geq \tilde{R}_{1,n}.
\]

Note that the set \( \tilde{X}_{n,\alpha} = \{x \in R^n : \tilde{l}_n(x) \leq T_{n,\alpha}\} \) is convex and symmetrical on any coordinate \( x_i \). Applying the Anderson’s lemma (see Ibragimov and Hasminskii, 1981) to coordinate cross-sections of the set \( \tilde{X}_{n,\alpha} \) we get the inequality \( P_{n,v}(\tilde{X}_{n,\alpha}) \leq P_{n,v}(X_{n,\alpha}) \), which implies for large enough \( n \)

\[
\beta_n(\psi_{n,\alpha}, \tilde{V}_n) \leq \min\{\delta, \sup_{v \in \tilde{V}_{n,Q_n}} P_{n,v}(\tilde{l}_n \leq T_{n,\alpha})
\]

(4.39)

where

\[
\tilde{V}_{n,Q_n} = \{v \in \tilde{V}_n \cap V^n_B : \max_i |v_i| \leq Q_n\}.
\]

By the (4.39) later we deal with the estimation of the probabilities \( P_{n,v}(\tilde{l}_n \leq T_{n,\alpha}) \)
( or the values \( P_{n,v}(\tilde{l}_n \leq T_{n,\alpha}) \) for \( \hat{H}_n \)-truncated statistics \( l_n \) with \( \hat{H}_n \geq H_n \) ) for \( v \in \tilde{V}_{n,Q_n} \). To simplicity we will omit often later the wave in the notations \( \tilde{l}_n, \tilde{V}_n \) and so on.

## 5 Upper bounds for \( \tau \geq 2 \)

For \( \hat{H}_n \)-truncated statistics \( l_n \) with \( \hat{H}_n = T_n - t_n/b_n \geq H_n \) ( \( \hat{H}_n = H_n \), if \( \tau < 3 \) ) and for \( v \in V_{n,Q_n} \) using (4.27), (4.30) one can assume

\[
\hat{w}_n = \sup_x |\hat{w}_n(x)| = w_n(\hat{H}_n) \to 0
\]

(5.40)

where \( \hat{w}_n(x) = w_n(x)1_{\{|x| \leq \hat{H}_n\}} \) are the \( \hat{H}_n \)-truncated items in the sum for \( \hat{l}_n = \sum_i \hat{w}_n(x_i) \). This implies the asymptotical \((0,1)\)-normality of the statistics \( (\hat{l}_n - \hat{m}_n)/(\hat{D}_n)^{1/2} \) under \( P_{n,v^{(n)}} \)-probability for any sequence \( v^{(n)} \in R^n \). Here \( \hat{m}_n = \hat{m}_n(v^{(n)}) \) and \( \hat{D}_n = \hat{D}_n(v^{(n)}) \) are the \( P_{n,v^{(n)}} \)-mean and \( P_{n,v^{(n)}} \)-variance of \( \hat{l}_n \). It is to obtain the relations:

\[
\Delta D_n = \hat{D}_n(v^{(n)}) - \hat{D}_n(0) = o(\Delta m_n),
\]

\[
\Delta m_n = \hat{m}_n(v^{(n)}) - \hat{m}_n(0) \geq 2n h_n^2 \sinh^2(b_n^2/2) \Phi(\hat{H}_n - 2b_n).
\]

13
In fact, the relations (5.40), (5.41) and the Central Limit Theorem (Petrov, 1981) imply that if $\Delta m_n \to \infty$, then $\hat{t}_n \to \infty$ and if $\Delta m_n = O(1)$, then $\hat{t}_n$ is $(\Delta m_n - v_n^2/2, v_n^2)$-asymptotically Gaussian under $P_{n,u(\cdot)}$-probability; $\Phi(T_n - b_n) \sim \Phi(\hat{H}_n - b_n)$ by the choosing $\hat{H}_n$ and the right-hand side in (5.42) is $u_n^2(1 + o(1))$. We have:

$$P_{n,u(\cdot)}(\hat{t}_n \leq T_{n,\alpha}) = \Phi\left(t_n - \frac{\Delta m_n}{u_n}\right) + o(1) \leq \Phi\left(t_n - u_n\right) + o(1).$$

To prove (5.41), (5.42) put

$$\mu_n(v) = \int_{|x| < \hat{H}_n} z_n(x) \left(d\Phi(x + v) - d\Phi(x)\right) = h_n \int_{|x| < \hat{H}_n} \xi(x, b_n) \xi(x, v) d\Phi(x),$$

$$\sigma_n^2(v) = \int_{|x| < \hat{H}_n} z_n^2(x) \left(d\Phi(x + v) - d\Phi(x)\right) = h_n \int_{|x| < \hat{H}_n} \xi^2(x, b_n) \xi(x, v) d\Phi(x).$$

By (5.40) one has

$$\Delta m_n = \sum_i \mu_n(v_i^{(n)}) + O \left(\sum_i \sigma_n^2(v_i^{(n)}) \right), \quad (5.43)$$

$$\Delta D_n = O \left(\sum_i \sigma_n^2(v_i^{(n)}) \right) + o(1).$$

Using the relations: if $b \to \infty$, $H \to \infty$, $H - |v| \to \infty$, then

$$\int_{|x| < H} \xi(x, b) \xi(x, v) d\Phi(x) \sim 2 \sinh^2(bv/2) \Phi(H - b - |v|), \quad (5.44)$$

$$\int_{|x| < H} \xi^2(x, b_n) \xi(x, v) d\Phi(x) \leq e^{b^2} \sinh^2(bv) \Phi(H - 2b - |v|)(1 + o(1)) \quad (5.45)$$

one can check that

$$\sum_i \sigma_n^2(v_i^{(n)}) = o \left(\sum_i \mu_n(v_i^{(n)}) \right)$$

and by (5.43) this implies (5.41). Also these imply that (5.40) follows from the inequality

$$\inf_{v \in V_n, Q_n} \sim 2 \sinh^2(b_n v_i/2) \Phi(\hat{H}_n - b_n - |v_i|) \geq 2n h_n^2 \sinh^2(b_n^2/2) \Phi(\hat{H}_n - 2b_n) \quad (5.46)$$

which follows from the

**Lemma 5.1** Denote $\Xi_n = \Xi_n^{p,q}(R_1, R_2, Q, p)$ the set of the collections $\bar{r} = (r_1, \ldots, r_n)$ of the probability measures on $(R^n, B)$:

$$\Xi_n = \left\{ \bar{r} : \sum_i \int |u|^p r_i(du) \geq R_{i,1, p}, \quad \sum_i \int |u|^p r_i(du) \leq R_{i,2, p}; \quad r_i([-Q_n, Q_n]) = 1 \right\}.$$

Let the values $h_n, b_n$ are defined by (1.13), $p > q, R_1 \leq R_2, b_n \to \infty$ and for some $d_n, \delta \in (0, 1)$ the following constraints hold:

$$b_n < Q_n \leq (1 - \delta) H_n + \sqrt{2 H_n b_n - 3 b_n^2}, \quad H_n > 2b_n - d_n, \quad d_n \to \infty, \quad d_n = o(b_n). \quad (5.47)$$
Put
\[ \Phi_n(r) = \int \phi_n(v)r(dv), \quad F_n(\bar{r}) = \sum_i \Phi_n(r_i) \]

where
\[ \phi(v) = \phi_n(v) = 2\sinh^2(b_n v/2)\Phi(H_n - b_n - |v|). \] (5.48)

Then for large enough \( n \) the following equality holds:
\[ \inf_{\bar{r} \in \Xi_n} F_n(\bar{r}) = F_n(\bar{r}^n) = n\Phi(\pi_n) = nh_n\phi(b_n) \] (5.49)

where
\[ \bar{r}^n = (\pi_n, \ldots, \pi_n), \quad \pi_n = \pi(h_n, b_n) = (1 - h_n)\delta_0 + \frac{h_n}{2}(\delta_{b_n} + \delta_{-b_n}) \].

In particular, for large enough \( n \) one has
\[ \inf_{v \in V_n \cup n} \sum_i \phi(v_i) \geq nh_n\phi(b_n) \]. (5.50)

**Proof of the Lemma** is given in sec. 8.

Note that the analogous to (5.49) equality for \( \tau > 2 \) and for \( \phi(v) = 2\sinh^2(b_n v/2) \) (which formally corresponds to (5.47), (5.48) with \( H_n = Q_n = \infty \)) follows from Ingster, 1990, 1993.

The Theorem 1 is proved.

### 6 Upper bounds for \( \tau \in (1, 2) \)

#### 6.1 The outline of the proof

By (4.39) it is enough to show that for any sequence \( v^{(n)} \in V_n \cup n \) one has
\[ \limsup(P_{n,v^{(n)}}(I_n \leq T^0_{\epsilon,\tau}(\alpha) - \beta_\tau(\alpha, P_{\pi^n})) \leq 0. \] (6.51)

Put
\[ L^0(t) = -2\Phi(-T_n(t)), \quad L(t) = L^0(t) + \Delta L_n(t) \]

where the values \( T_n(t) \) are defined by (4.29) and
\[ \Delta L_n(t) = -\sum_i P_{1,\pi^{(n)}}(w_n(x) > t) - P_{1,0}(w_n(x) > t) \]
= \[ -\sum_i \left( \Phi(-T_n(t) + |v^{(n)}_i|) + \Phi(-T_n(t) - |v^{(n)}_i|) \right) \]. (6.52)

It is clear that \( \Delta L_n(t) \leq 0 \). Also one can easily check that \( \Delta L_n(t) \to 0 \) as \( t \to \infty \) and for large enough \( n \) and any \( t_0 > 0 \) the functions \( \Delta L_n(t) \) are bounded from below on \( t \geq t_0 \) and their derivatives are positive and bounded on \( t \geq t_0 \). Thus the
set of the functions $\{\Delta L_n(t)\}$ are equicontinuous in $C[t_0, \infty)$ for any $t_0 > 0$ and we can assume that for every $t > 0$

$$\Delta L_n(t) \to \Delta L(t)$$  \hspace{1cm} (6.53)

where $\Delta L(t)$ is continuous on $(0, \infty)$ and the properties of Levi spectrum hold:

$$\Delta L(t) \leq 0, \ \Delta L(t) \to 0 \text{ as } t \to \infty, \ \Delta L(t) \text{ nonincreasing on } t > 0$$

and (we will show below) for any $\delta > 0$

$$\int_{0}^{\delta} t^2 d\Delta L(t) < \infty.\hspace{1cm} (6.54)$$

Put

$$\mu_n = \sum_i \mu_{n,i} = 2h_n \sum_i \sinh^2(b_n v^{[n]}/2) \Phi(T_n - b_n - |v^{[n]}_i|).\hspace{1cm} (6.55)$$

The outline of the proof is following. We show that if $\mu_n \to \infty$, then $l_n \to \infty$ under $P_{n,v^{[n]}}$-probability. Let $\mu_n = O(1)$. Then, by pass to subsequence, we can find such constant $b \geq 0$ that the limit $P_{n,v^{[n]}}$-distribution of the statistics $l_n$ is the distribution of the sum $\zeta = \zeta^0 + \Delta \zeta$. Here $\zeta^0$ and $\Delta \zeta$ are an independent infinite divisible random variables. The variable $\zeta^0$ corresponds to the limit $P_0$-distribution of the statistics $l_n$ and is described in sec. 2.2. The variable $\Delta \zeta$ has not Gaussian component also and is supported on the half-line $(b, \infty)$ (it means that the characteristic function $\phi_{\Delta \zeta}(z)$ of the $\Delta \zeta$ is of the form:

$$\log \phi_{\Delta \zeta}(z) = ibz + \int_0^{\infty} (\exp(itz) - 1) d\Delta L(t).\hspace{1cm} (6.56)$$

Then we obtain the relation

$$\Delta L(t) = L^\Delta(t) + \Lambda(t), \ t > 0\hspace{1cm} (6.57)$$

$$\Delta L(t) \leq 0, \ d\Delta L(t)/dt \geq 0, \ \Delta L(t) \to 0 \text{ as } t \to \infty$$

and the relation (6.54) implies the analogous relation for $\Lambda(t)$: for any $\delta > 0$

$$\int_{0}^{\delta} t^2 d\Lambda(t) < \infty.\hspace{1cm} (6.58)$$

These relations imply the equality

$$\zeta = \zeta^0 + \zeta^\delta + \eta = \zeta^1 + \eta\hspace{1cm} (6.59)$$

where the random variables $\zeta^0$, $\zeta^\delta$, $\eta$ are independent, $\zeta^1 = \zeta^0 + \zeta^\delta$ corresponds to the limit distribution of $l_n$ under the Bayesian alternatives $P_\alpha$ and $\eta \geq b \geq 0$ with the probability 1. By (6.59) and by the Theorem 2 in Ingster, 1997 one has

$$P_{n,v^{[n]}}(l_n \leq T^0_{c,\tau}(\alpha)) \leq P(\zeta^1 \leq T^0_{c,\tau}(\alpha)) + o(1) = \beta_n(\alpha, P_\alpha) + o(1)$$

which imply (6.51) and the upper bounds of the Theorem 2.
6.2 The study of the limit distribution of \( l_n \)

To realize the outline above introduce the functions

\[
\mu_n(t) = \sum_i \mu_{n,i}(t) = 2h_n \sum_i \int |x| < T_n(t) \xi(x, b_n) \xi(x, v_i^{(n)}) d\Phi(x),
\]

\[
\sigma_n^2(t) = \sum_i \sigma_{n,i}^2(t) = 2h_n^2 \sum_i \int |x| < T_n(t) \xi^2(x, b_n) \xi(x, v_i^{(n)}) d\Phi(x)
\]

and put

\[
\sigma_n^2 = \sum_i \sigma_{n,i}^2 = 2h_n^2 e^{b_n^2} \sum_i \sinh^2(b_n v_i^{(n)}) \Phi(T_n - 2b_n - |v_i^{(n)}|).
\]

Using the relations (5.44), (5.45) and (4.28) one can check that

\[
\mu_{n,i}(t) = \begin{cases} 
\mu_{n,i}, & \text{if } |v_i^{(n)}| \leq T_n - b_n, \\
\mu_{n,i}(e^t - 1)^{b_n(v_i^{(n)})/b_n + 1 - \tau_n}, & \text{if } |v_i^{(n)}| > T_n - b_n
\end{cases}
\]

(6.60)

and for large enough \( n \)

\[
\sigma_{n,i}^2(t) \leq B \sigma_{n,i}^2(e^t - 1)^{b_n(v_i^{(n)})/b_n + 2 - \tau_n}
\]

( here and later we denote \( B \) some positive constants, may be, different, which do not depend on \( n \)). Also one can check that

\[
\sigma_n^2 = \begin{cases} 
o(\mu_{n,i}(t)), & \text{if } |v_i^{(n)}| \leq T_n - b_n, \\
o(\mu_{n,i}(t)), & \text{if } |v_i^{(n)}| > T_n - b_n
\end{cases}
\]

which imply for large enough \( n \) and small enough \( t > 0 \) the relation

\[
\sigma_n^2(t) \leq B \mu_n(t)(t + o(1)).
\]

(6.61)

Let us estimate the differences of the means and of the variances

\[
\Delta E_n = E_{n,v^{(n)}} l_n - E_{n,0} l_n, \quad \Delta D_n = D_{n,v^{(n)}} l_n - D_{n,0} l_n.
\]

It is clear that

\[
\Delta E_n = \sum_i \int w_n(x) \xi(x, v_i^{(n)}) d\Phi(x).
\]

(6.62)

Denote

\[
\bar{D}_{n,v^{(n)}} = \sum_i \int w_n^2(x) d\Phi(x + v_i^{(n)}), \quad \bar{D}_{n,0} = \sum_i \int w_n^2(x) d\Phi(x).
\]

By \( E_{n,0} l_n = n E_{1,0} w_n(x) = O(1) \) it is clear that \( \Delta D_n \leq \Delta \bar{D}_n + o(1) \) and

\[
\Delta \bar{D}_n = \bar{D}_{n,v^{(n)}} - \bar{D}_{n,0} = \sum_i \int w_n^2(x) \xi(x, v_i^{(n)}) d\Phi(x).
\]

(6.63)
For any \( t > 0 \) put

\[
\Delta E_n = \Delta E_n^+(t) + \Delta E_n^-(t), \quad \Delta \tilde{D}_n = \Delta \tilde{D}_n^+(t) + \Delta \tilde{D}_n^-(t)
\]

where the items with the index \(+\) and \(-\) correspond to the sums of the integrals in (6.62) and (6.63) over the sets \(|x| > T_n(t)\) and \(|x| < T_n(t)\).

Let us obtain the relations

\[
\begin{align*}
\Delta E_n^+(t) &= O(1), \quad \Delta \tilde{D}_n^+(t) = O(1), \quad \text{(6.64)} \\
\Delta E_n^-(t) &= \mu_n(t)(1 + O(t + o(1))), \quad \text{(6.65)} \\
\Delta \tilde{D}_n^-(t) &= O(\mu_n(t)). \quad \text{(6.66)}
\end{align*}
\]

To obtain (6.64), note the equality:

\[
2\xi(x, v)d\Phi(x) = d\Phi(x + |v|) + d\Phi(x - |v|) - 2d\Phi(x) \quad \text{(6.67)}
\]

which implies the equality analogous to (6.52):

\[
\Delta E_n^+(t) = A_n(t) + B_n(t) - 2C_n(t) \quad \text{(6.68)}
\]

Here by (4.27), (4.30), (4.28) one has

\[
\begin{align*}
A_n(t) &\sim \sum_i \left( \frac{T_n - |v_i^{[n]}|}{b_n} \right) \Phi(|v_i^{[n]}| - T_n) \int_{u > \epsilon^t - 1} u^{-(\tau + 1 - |v_i^{[n]}|/b_n)} \log(1 + u) du, \\
B_n(t) &\sim \sum_i \left( \frac{T_n + |v_i^{[n]}|}{b_n} \right) \Phi(-|v_i^{[n]}| - T_n) \int_{u > \epsilon^t - 1} u^{-(\tau + 1 + |v_i^{[n]}|/b_n)} \log(1 + u) du, \\
C_n(t) &\sim c\tau \int_{u > \epsilon^t - 1} u^{-(\tau + 1)} \log(1 + u) du
\end{align*}
\]

where the boundedness of the values \( A_n(t), \ B_n(t), \ C_n(t) \) follows from the boundedness of the integrals above (for \(|v_i^{[n]}|/b_n \leq \eta < \tau\) by the definition of the set \( V_{n, Q_n} \) and from the boundedness of the sums \( \sum_i \Phi(-T_n + |v_i^{[n]}|) \) by (6.52), (6.53).

The boundedness of the values \( \Delta \tilde{D}_n^+(t) \) follows from the analogous estimations.

The relations (6.65), (6.66) follow from (6.61) and the relation \( \log(1 + z) = z + O(z^2) \) for \(-1 < z < B\).

Assume \( \mu_n \to \infty \). Then by the boundedness of the values \( E_n, 0 l_n, \ D_n, 0 l_n \) and from the relations (6.60), (6.62) - (6.66) one has

\[
E_{n, v^{[n]}(t)} l_n \asymp \mu_n \to \infty, \quad D_{n, v^{[n]}(t)} l_n \leq B E_{n, v^{[n]}(t)} l_n
\]

and using the Chebyshev inequality one has \( l_n \to \infty \) under \( P_{n, v^{[n]}(t)} \)-distribution.

Assume \( \mu_n = O(1) \). Let us obtain the relations:

\[
\lim_{n \to \infty} \sum_i P_{1, v_i^{[n]}} \{ x : w_n(x) > t \} = - (L_0(t) + \Delta L(t)) \quad \text{for any} \quad t > 0; \quad (6.69)
\]

\[
\lim_{t \to \infty} \lim_{n \to \infty} \Delta \tilde{D}_n^-(t) = 0, \quad \text{(6.70)}
\]

\[
\lim_{t \to 0} \lim_{n \to \infty} \Delta E_n^-(t) \geq 0, \quad \text{(6.71)}
\]

\[
\lim_{t_2 \to 0} \lim_{t_1 \to 0} \lim_{n \to \infty} (\Delta E_n^-(t_2) - \Delta E_n^-(t_1)) = 0. \quad \text{(6.72)}
\]
By pass to subsequence in (6.71) one can assume that there exist the limit \( b \geq 0 \) of the left-hand side (6.71). Then the relations (6.69) - (6.72) imply that the limit \( P_{n,0}(n) \)-distribution of the statistics \( \xi_n \) is the distribution of the sum \( \xi = \xi_0 + \Delta \xi \). In fact (see Petrov, 1981), (6.69) implies the necessary form of the Levi spectrum, (6.70) and analogous relation (4.7) in Ingster, 1997 imply that the limit \( P_{n,0(n)} \)-distribution of \( \xi_n \) has no Gaussian component and (6.54) holds.

Let us consider the component \( \gamma \). One has the equality: \( \gamma = \gamma^0 + \Delta \gamma \) where for any \( t > 0 \)

\[
\Delta \gamma = \lim_{n \to \infty} \sum_i \int_{|w_n| < t} w_n(x) \xi(x, v^{[n]}_i) d\Phi(x) - \int_{+0}^{t} \frac{x^3}{1 + x^2} d\Delta L(x) + \int_{t}^{\infty} \frac{x}{1 + x^2} d\Delta L(x). \tag{6.73}
\]

Let \( t \to 0 \) in (6.73). Then the relations (6.71), (6.54) imply that the limit of the first item in right-hand side is nonnegative and the limit of the second item is 0. Also by (6.69), (6.72) one can pass to the limit in the third item by:

\[
\lim_{t \to 0} \int_{+0}^{t} \frac{x}{1 + x^2} d\Delta L(x) = \lim_{t_2 \to 0} \lim_{t_1 \to 0} \int_{t_1}^{t_2} x d\Delta L(x) =
\lim_{t_2 \to 0} \lim_{t_1 \to 0} \lim_{n \to \infty} (\Delta E^-_n(t_2) - \Delta E^-_n(t_1)) = 0.
\]

These imply the equality

\[
\Delta \gamma = b + \int_{+0}^{\infty} \frac{x}{1 + x^2} d\Delta L(x)
\]

which is equivalent to (6.56).

### 6.3 Proof of the (6.69) - (6.72)

The relation (6.69) follows from (6.53) and from the analogous relation (4.2) in Ingster, 1997 for the limit \( P_{n,0} \)-spectrum \( L_0 \). The relations (6.60), (6.61) imply the estimators

\[
\Delta \tilde{D}^-(t) \leq B \sigma_n^2(t) \leq B \mu_n(t + o(1))
\]

which imply (6.70). The relation (6.71) follows from (6.65), (6.66), (6.60).

To prove (6.72) let us consider the equality

\[
\Delta E^-_n(t_2) - \Delta E^-_n(t_1) = \Sigma_{n,1}(t_1, t_2) + \Sigma_{n,2}(t_1, t_2).
\]

Here \( \Sigma_{n,1}(t_1, t_2) \), \( l = 1, 2 \) correspond to the sums of the items in (6.62) with such \( i \) that \( |v_i^{[n]}| \leq A_n \) (for \( l = 1 \)) and \( |v_i^{[n]}| \in (A_n, Q_n) \) (for \( l = 2 \)) where \( A_n = \delta_n/T_n \), \( \delta_n \to 0 \). By \( |\xi(x, v)| \leq \delta^2_n(1 + o(1))/2 \) for \( |v| \leq A_n \), \( |x| \leq T_n(t_2) \), using (4.27), (4.30) one has for any \( t_2 > t_1 > 0 \):

\[
\Sigma_{n,1}(t_1, t_2) \leq n \delta^2_n \int_{T_n(t_1)}^{T_n(t_2)} |w_n(x)| d\Phi(x)(1 + o(1)) \sim \delta^2_n c t \int_{e^{t_1-1}}^{e^{t_2-1}} |\log(1 + u)| u^{-(r+1)} du \to 0 \text{ as } n \to \infty. \tag{6.74}
\]
To estimate $\Sigma_{n,2}(t_1, t_2)$ denote $m_n(A_n)$ the number of the items in this sum. By (1.13) one has

$$m_n(A_n) \leq A_n^{-q} \sum_i |v_i^{(n)}|^q \leq (b_n/A_n)^q n h_n = h_n^2 \delta_n^{-q} n h_n$$

and by (4.32) for any $\epsilon_1 > 0$ one can choose such $\delta_n = n^{-\epsilon_0}$ and $\epsilon_0 > \epsilon_1/q$ that

$$m_n(A_n) \leq B n^{1+\epsilon_1} h_n = o(n). \quad (6.75)$$

By analogy with (6.52), (6.68) put

$$\Sigma_{n,2}(t_1, t_2) = A_n(t_1, t_2) + B_n(t_1, t_2) - 2C_n(t_1, t_2)$$

where $A$, $B$, $C$ are the sums which correspond to the items in the right-hand side of (6.67). By analogy with the estimation of the values $\Delta E_n^+(t)$ one can obtain the estimators: for any $t_2 > t_1 > 0$

$$C_n(t_1, t_2) \leq (1 + o(1)) c \tau m_n(A_n) n^{-1} \phi_1(t_1, t_2) \to 0 \text{ as } n \to \infty$$

where

$$\phi_1(t_1, t_2) = \int_{e^{t_1-1}}^{e^{t_1-1}} |\log(1 + u)| u^{-(\tau+1)} du$$

and analogously $B_n(t_1, t_2) \to 0$. To estimate $A_n(t_1, t_2)$ put

$$A_n(t_1, t_2) = A_{n,1}(t_1, t_2) + A_{n,2}(t_1, t_2).$$

Here the values $A_{n,i}(t_1, t_2)$, $i = 1, 2$ correspond to the sums of the items in with such $i$ that $|v_i^{(n)}| \in (A_n, b_n(1-\epsilon)]$ (for $i = 1$) and $|v_i^{(n)}| \in (b_n(1-\epsilon), Q_n]$ (for $i = 2$) where $0 < \epsilon < \min(2-\tau, 2\tau - 2)$. Using (4.27), (4.30) (6.75) one has for small enough $t_2 > t_1 > 0$

$$A_{n,1}(t_1, t_2) \leq B m_n(A_n) b_n^{-1} \exp\left(-(T_n - b_n(1-\epsilon))^2/2\right) \phi_1(t_1, t_2) \to 0 \text{ as } n \to \infty$$

by for small enough $\epsilon_1 > 0$

$$m_n(A_n) e^{-(T_n - b_n(1-\epsilon))^2/2} \leq m_n(A_n) e^{-\epsilon_1^2 \tau (n-1-\epsilon/2)} \to 0.$$

Also one has for small enough $t_2 > t_1 > 0$

$$A_{n,2}(t_1, t_2) \leq B_n \phi_e(t_1, t_2); \quad B_n \leq B \sum_i \Phi(T_n - |v_i^{(n)}|) = O(1) \text{ as } n \to \infty$$

where

$$\phi_e(t_1, t_2) = \int_{e^{t_1-1}}^{e^{t_1-1}} |\log(1 + u)| u^{-(\tau+\epsilon)} du \sim \int_{t_1}^{t_2} u^{1-\tau-\epsilon} du$$

and by the choosing $\epsilon$

$$\lim_{t_2 \to 0} \lim_{t_1 \to 0} \phi_e(t_1, t_2) \to 0.$$
The estimators above imply (6.72).
Now it is necessary to obtain the relation (6.57). By pass $n \to \infty$ this relation follows from the inequalities
\[
\Delta L_n \leq L_{\pi_n}^\Delta, \quad \frac{d}{dt} \Delta L_n \geq \frac{d}{dt} L_{\pi_n}^\Delta
\] (6.76)
where $\Delta L_n$ is defined by (6.52) and (see Ingster, 1997, the relation (4.11))
\[
L_{\pi_n}^\Delta(t) = n(\rho_{1,0}(w_n(x) > t) - \rho_{1,\pi_n}(w_n(x) > t)) \to L^\Delta(t).
\]
The following Lemmas imply the inequalities (6.76).

**Lemma 6.1** Let us change the constraints (5.47) of the Lemma 5.1 onto following:
for some $B \geq 1$
\[
H_n - b_n \geq d_n \to \infty, \quad BH_n \geq Q_n > b_n;
\] (6.77)
and change the functionals (5.48) onto
\[
\phi(v) = \Phi(-H_n + v) + \Phi(-H_n - v) - 2\Phi(-H_n).
\] (6.78)
Then for large enough $n$ the equality (5.49) and the inequality (5.50) hold.

**Lemma 6.2** Let us change the constraints (5.47) of the Lemma 5.1 onto following:
\[
H_n - b_n \geq d_n \to \infty, \quad (2 - \delta)H_n - b_n \geq Q_n > b_n;
\] (6.79)
and change the functionals (5.48) onto
\[
\phi(v) = \exp(-(H_n - v)^2/2) + \exp(-(H_n + v)^2/2) - 2\exp(-H_n^2/2).
\] (6.80)
Then for large enough $n$ the equality (5.49) and the inequality (5.50) hold.

**Proof of the Lemmas** is given in sec 8.
The upper bounds of the Theorem 2 are proved.

7 The study of the tests (2.23): upper bounds and consistent properties

Put $\lambda_{n,\alpha} = \lambda_{n,\alpha}(b_n, h_n) = nh_n \Phi(b_n - H_{n,\alpha})$.

**Lemma 7.1**

1. Assume (i): $b_n - H_{n,\alpha} \to \infty$; or (ii): $nh_n \to \infty$ and $\lambda_{n,\alpha} \to \infty$. Then
\[
\beta_n(\psi_{n,\alpha}, V_n) \to 0.
\]
2. Assume $nh_n \to \infty$ and $\lambda_{n,\alpha} = O(1)$. Then
\[
\beta_n(\psi_{n,\alpha}, V_n) \leq (1 - \alpha) \exp(-\lambda_{n,\alpha}) + o(1).
\] (7.81)
3. Assume $nh_n = O(1)$. Then
\[
\beta_n(\psi_{n,\alpha}, V_n) \leq (1 - \alpha) \Phi(\sqrt{2\log n - b_n})^{nh_n} + o(1).
\] (7.82)
Proof of the Lemma. By \( p > q \) one has for all \( v \in V_n \)

\[
R_{n,1}^p \leq \sum_i |v_i|^p \leq \max_i |v_i|^{p-q} \sum_i |v_i|^q \leq \max_i |v_i|^{p-q} R_{n,2}^q.
\]

This relations and (1.13) imply

\[
\inf_{v \in V_n} \max_i |v_i| \geq b_n = \left(\frac{R_{n,1}^p}{R_{n,2}^q}\right)^{1/(p-q)}. \tag{7.83}
\]

In analogy with (4.36) using (7.83) one has

\[
\beta_n(\psi_{\alpha,\alpha}, V_n) \leq \Phi(H_{n,\alpha} - \inf_{v \in V_n} \max_i |v_i|) \leq \Phi(H_{n,\alpha} - b_n) \to 0
\]
as \( b_n - H_{n,\alpha} \to \infty \).

Let \( nh_n \to \infty \). One can assume that

\[
H_{n,\alpha} \geq b_n + d_n \text{ for some sequence } d_n \to \infty, \quad d_n = o(b_n). \tag{7.84}
\]

In fact, put \( V_n(t) = V_n^{\alpha,q}(tR_{n,1}, tR_{n,2}), \ t \in (0,1) \) and note that

\[
\beta_n(\psi_{\alpha,\alpha}, V_n) \leq \beta_n(\psi_{\alpha,\alpha}, V_n(t)).
\]

One can get this relation from the proof of Anderson’s lemma (see Ibragimov and Hasminskii, 1981). The direct proof follows from the equality (in analogy with (4.37))

\[
\beta_n(\psi_{\alpha,\alpha}, V_n) = \prod_i \left(1 - \Phi(H_{n,\alpha} - |v_i|) - \Phi(-H_{n,\alpha} - |v_i|)\right) \tag{7.85}
\]

and from the decrease on \( |v_i| \) of the functions under the product. The set \( V_n(t) \) is corresponding to the values \( h_n(t) = h_n, b_n(t) = tb_n \). Thus, if \( \limsup H_{n,\alpha} - b_n < \infty \), then one can choose such \( t = t_n < 1 \) that (7.84) holds and \( \lambda_{n,\alpha}(b_n(t_n), h_n) \to \infty \).

Put \( Q_n = H_{n,\alpha} + d_n/2 \). Assume \( v \in V_n, \max_i |v_i| \geq Q_n \). Then \( \beta_n(\psi_{\alpha,\alpha}, V_n) \to 0 \) by (4.36).

Assume \( v \in V_n, \max_i |v_i| < Q_n \). Then using (7.85) one has

\[
\beta_n(\psi_{\alpha,\alpha}, v) = (1 - \alpha) \prod_i \left(1 - \frac{\phi(|v_i|, H_{n,\alpha})}{1 - 2\Phi(-H_{n,\alpha})}\right) \tag{7.86}
\]

\[
\leq (1 - \alpha) \exp \left(-\frac{F(v, H_{n,\alpha})}{1 - 2\Phi(-H_{n,\alpha})}\right)
\]

where

\[
F(v, H) = \sum_i \phi(v_i, H), \ \phi(t, H) = \Phi(-H + t) + \Phi(-H - t) - 2\Phi(-H).
\]

Using the Lemma 6.1 for \( H_n = H_{n,\alpha} \) one has \( F(v, H_{n,\alpha}) \geq \lambda_{n,\alpha} \) which imply

\[
\beta_n(\psi_{\alpha,\alpha}, v) \leq (1 - \alpha) \exp(-\lambda_{n,\alpha}(1 + o(1)));
\]

22
Let \( nh_n = O(1) \). One can assume that \( H_n, - b_n = O(1) \). Then analogously to (7.86) we have:
\[
\beta_n(\psi_n, v) = (1 - \alpha) \exp(-F(v, H_n)), \quad F(v, H) = \sum_i \phi(v_i, H)
\]
where
\[
\phi(v, H) = \log \left( \frac{P_{1,0}([-H, H])}{P_{1,v}([-H, H])} \right) = \log(\Phi(H) - \Phi(-H)) - \log(\Phi(H - v) - \Phi(-H - v)).
\]

(7.87)

Then the inequality (7.82) follows from the

**Lemma 7.2** Let us change the constraints (5.47) of the Lemma 5.1 onto following:
\[
H_n - b_n = O(1), \quad b_n + O(1) \geq Q_n > b_n;
\]

and change the functionals (5.48) onto (7.87). Then for large enough \( n \) the equality (5.49) and the inequality (5.50) hold.

*Proof of the Lemma 7.2* is given in sec 8.

The Lemma 7.1 is proved.

The following Lemma which has been proved in Ingster, 1997.

**Lemma 7.3** Let \( k_n = nh_n \to \infty \).

1. Let \( \tau_n < \infty, \quad \lambda_n \to \infty \). Then \( \lambda_n, \alpha \to \infty \).
2. Let \( \tau = 1, \quad \lambda \to 1 \). Then \( \lambda_n, \alpha \to \lambda + o(1) \).

We get the upper bounds and consistent properties of the Theorem 3 from the

Lemmas 7.1, 7.3 and from the simple remark: if \( \tau \in (1, \infty) \), then using (4.26), (4.28) one has
\[
c_n = 2\Phi(-T_n) \sim \lambda_n \frac{\tau - 1}{\tau} \sim \lambda_n.
\]

The Theorem 3 is proved.

## 8 Proof of the Lemmas 5.1-7.2

We give the outline of the proofs and omit some simple calculations.

The linear convex problems of minimization are considered in the Lemmas: to minimized the functional
\[
\inf_{\bar{\varphi} \in \Xi_n} F(\bar{\varphi}); \quad F(\bar{\varphi}) = \sum_{i=1}^n \int \phi(v) r_i(\varphi)
\]
where the convex set \( \Xi_n = \{\bar{\varphi} = (r_1, ..., r_n)\} \) of collections of the probability measures \( r_i \) on the real line is defined by the constraints: \( r_i([-Q_n, Q_n] = 1, \quad i = 1, ..., n \) and
\[
\sum_{i=1}^n \int \phi_1(v) r_i(\varphi) \geq H_1, \quad \sum_{i=1}^n \int \phi_2(v) r_i(\varphi) \leq H_2.
\]

23
Here the functions $\phi = \phi_n$ are defined by (5.48), (6.78), (6.80), (7.87), $\phi(t) = \phi(-t) \geq 0$, $\phi(0) = 0$ and $\phi_1(v) = |v|^p$, $\phi_2(v) = |v|^q$, $H_1 = H_{1,n} = R^q_n$, $H_2 = H_{2,n} = R^{2q}_{2,n}$.

By the symmetry of the problems one can find the infimum on the collections $\mathfrak{r}^* = (r^*, \ldots, r^*) \in \Sigma_n$ of the equal symmetrical measures $r^*$. Also using the method of subdifferentials and the Theorem by Kuhn and Tucker (see, for example, Ioffe and Tikhomirov (1976), pp. 76-77) one can get the sufficient conditions of infimum: there exist such $\lambda = \lambda_n > 0$, $\mu = \mu_n > 0$, $\eta = \eta_n$ that the following relations hold:

$$\phi(v) - \lambda \phi_1(v) + \mu \phi_2(v) \geq \eta \quad \text{for all} \quad v \in [-Q_n, Q_n]$$

(8.89)

and

$$r^*\{v : \phi(v) - \lambda \phi_1(v) + \mu \phi_2(v) = \eta\} = 1.$$  

(8.90)

It is enough to check that $r^* = \pi(b_n, h_n)$ satisfies to (8.90) and (8.89) holds for some $\lambda > 0$, $\mu > 0$, $\eta$. The relation (8.90) implies the equality in (8.89) for $v = 0$, $v = b$ and $v = -b$; $b = b_n \to \infty$ as $n \to \infty$.

Put $\eta = 0$ and

$$\lambda = \frac{b \phi'(b) - q \phi(b)}{b^p(p-q)}, \quad \mu = \frac{b \phi'(b) - p \phi(b)}{b^q(p-q)}$$

(8.91)

which imply the necessary equalities in (8.89). Thus we need to check the inequalities: $\lambda > 0$, $\mu > 0$ and

$$\psi(v) = \phi(v) + (v/b)^p \frac{b \phi'(b) - p \phi(b)}{p-q} - (v/b)^q \frac{b \phi'(b) - q \phi(b)}{q-q} \geq 0, \quad 0 \leq v \leq Q_n.$$  

(8.92)

For large enough $b = b_n$ the inequalities $\lambda > 0$, $\mu > 0$ follow from the relations:

$$\phi'(b) > 0, \quad \eta(b) = \phi(b)/b \phi'(b) \to 0 \quad \text{as} \quad b \to \infty.$$  

(8.93)

The relations (8.93) hold under assumptions of the Lemmas.

By $f(t) = (t^p - t^q)/(p-q) > 0$, $t \in (0, 1)$, $f(1-z) \sim z$ as $z \to 0$ and $\phi(v) \geq 0$, one can easily check that (8.92) holds, if $v \in \Delta_n^- = (0, b_n^-)$ where $b_n^- = b_n(1 - B \eta(h_n))$ for large enough $B = B(p, q)$.

Fix small enough $\delta > 0$. Assume $Q_n \geq b_n^+ = b_n + \delta d_n$ (this is possible under assumptions of the Lemmas 5.1-6.2) and $v \in \Delta_n^+ = [b_n^+, Q_n]$. To satisfy (8.92) for $v \in \Delta_n^+$ it is enough the following: for some $B > 0$

$$Bb_n \geq Q_n, \quad \phi(v) \geq \phi(b_n^+), \quad v \in \Delta_n; \quad b_n \phi'(b_n)/\phi(b_n^+) \to 0 \quad \text{as} \quad b_n \to \infty.$$  

(8.94)

Under assumptions of the Lemmas 5.1-6.2 using (4.28) one can easily check that (8.94) hold. Note that the relation $\phi(v) \geq \phi(b_n^+)$, $v \in \Delta_n$ in (8.94) follows from the constraints on $Q_n$ in the Lemmas 5.1, 6.2 and from the increase of $\phi(v)$ on $v$ in the Lemma 6.1.

Let $v \in \Delta_n^0 = (b_n^-, b_n^+)$ where $b_n^* = \min(Q_n, b_n^+)$ (note that $b_n^* = Q_n$ under the assumptions of the Lemma 7.2). The relations (8.91) imply the tangency of the
functions $\psi(v)$ and $v = 0$ at the point $v = b_n$. The inequality (8.92) follows from the convexity of $\psi(v)$, $v \in \Delta^0$. To convexity it is enough the following:

$$\phi''_n = \inf_{v \in \Delta^0} \phi''(v) > 0, \phi'(b_n)/b_n \phi''_n \to 0 \text{ as } b_n \to \infty \quad (8.95)$$

One can easily check (8.95) under the assumption of the Lemmas. In fact, $\phi''_n = \phi''(b_n)$ under assumptions of the Lemmas 5.1-6.2; $\phi''_n \approx \phi'(b_n) \approx 1$ under assumptions of the Lemma 7.2.

The Lemmas are proved.
