Introduction

- The MRI experiment
- Diffusion weighted/tensor imaging
- Fiber orientation mapping and fiber tracking
- Applications at Cornell Medical College
- White matter fiber tracking in inferior brain regions and cervical spinal cord
- Fiber crossings and non-Gaussian diffusion

The MRI experiment

*“There is nothing that nuclear
spins will not do for you, as
long as you treat them as
human beings”*

(Erwin L. Hahn 1949)

Larmor equation

$$\omega_0 = \gamma B_0$$

Constant gradients in object:

$$\omega(x, y, z) = \gamma (B_0 + \text{grad } B^*(x, y, z))$$

Diffusion weighted imaging (DWI)

Bipolar pulse field gradient method

Theory

- Rigorous approach:

Add diffusion term to Bloch equations:
Bloch-Torrey equation

- More convenient approach:

Start with probability distribution of spins
and use diffusion equation

1-D approach to keep the math simple:

δ = length of diffusion gradients

Δ = duration of diffusion gradients

$P(z)$ = probability distribution

$P(z_2, z_1, \Delta)$ = propagator: probability that after a time Δ the spins are at z_2 when they were at z_1 before

Assume $\delta \ll \Delta$, then

First gradient: dephasing $\Phi_1 = \gamma \int_0^\delta G z_1 dt = \gamma G z_1 \delta$

2nd gradient: dephasing $\Phi_2 = \gamma \int_\Delta^{\Delta+\delta} G z_2 dt = \gamma G z_2 \delta$

Net dephasing $\Phi_2 - \Phi_1 = \gamma G \delta (z_2 - z_1)$

Taking into account the conditional probability (propagator) that after a time Δ the spins are at z_2 when they were at z_1 before, the signal is

$$S = S_0 \int dz_1 P(z_1) \int \exp(i\gamma\delta G(z_2 - z_1)) P(z_2, z_1, \Delta) dz_2 \quad (*)$$

Isotropic diffusion process:

$$\partial P(z_2, z_1, t) / \partial t = D \Delta P(z_2, z_1, t) \quad (**)$$

P is Gaussian at $t=\Delta$:

$$P(z_2, z_1, \Delta) = (4\pi\Delta D)^{-1/2} \exp(-(z_2 - z_1)^2 / 4\Delta D)$$

[Can be checked by re-insertion into (**), homework]

Combining this with (*), and using Einstein's law $\langle z^2 \rangle = 2Dt$, we obtain

$$S \propto \exp(-(\gamma\delta G)^2 \Delta D) = \exp(-(\gamma\delta G)^2 \langle z^2 \rangle / 2)$$

[requires integration in the complex domain, not trivial, refer to integral table]

- We only consider lumped parameter model

$$S = S_0 \exp(-bD),$$

where b is the b -value, fixed in experiment by

- Stejskal-Tanner equation: $b = (g\gamma\delta)^2(\Delta - \delta/3)$

- Example:

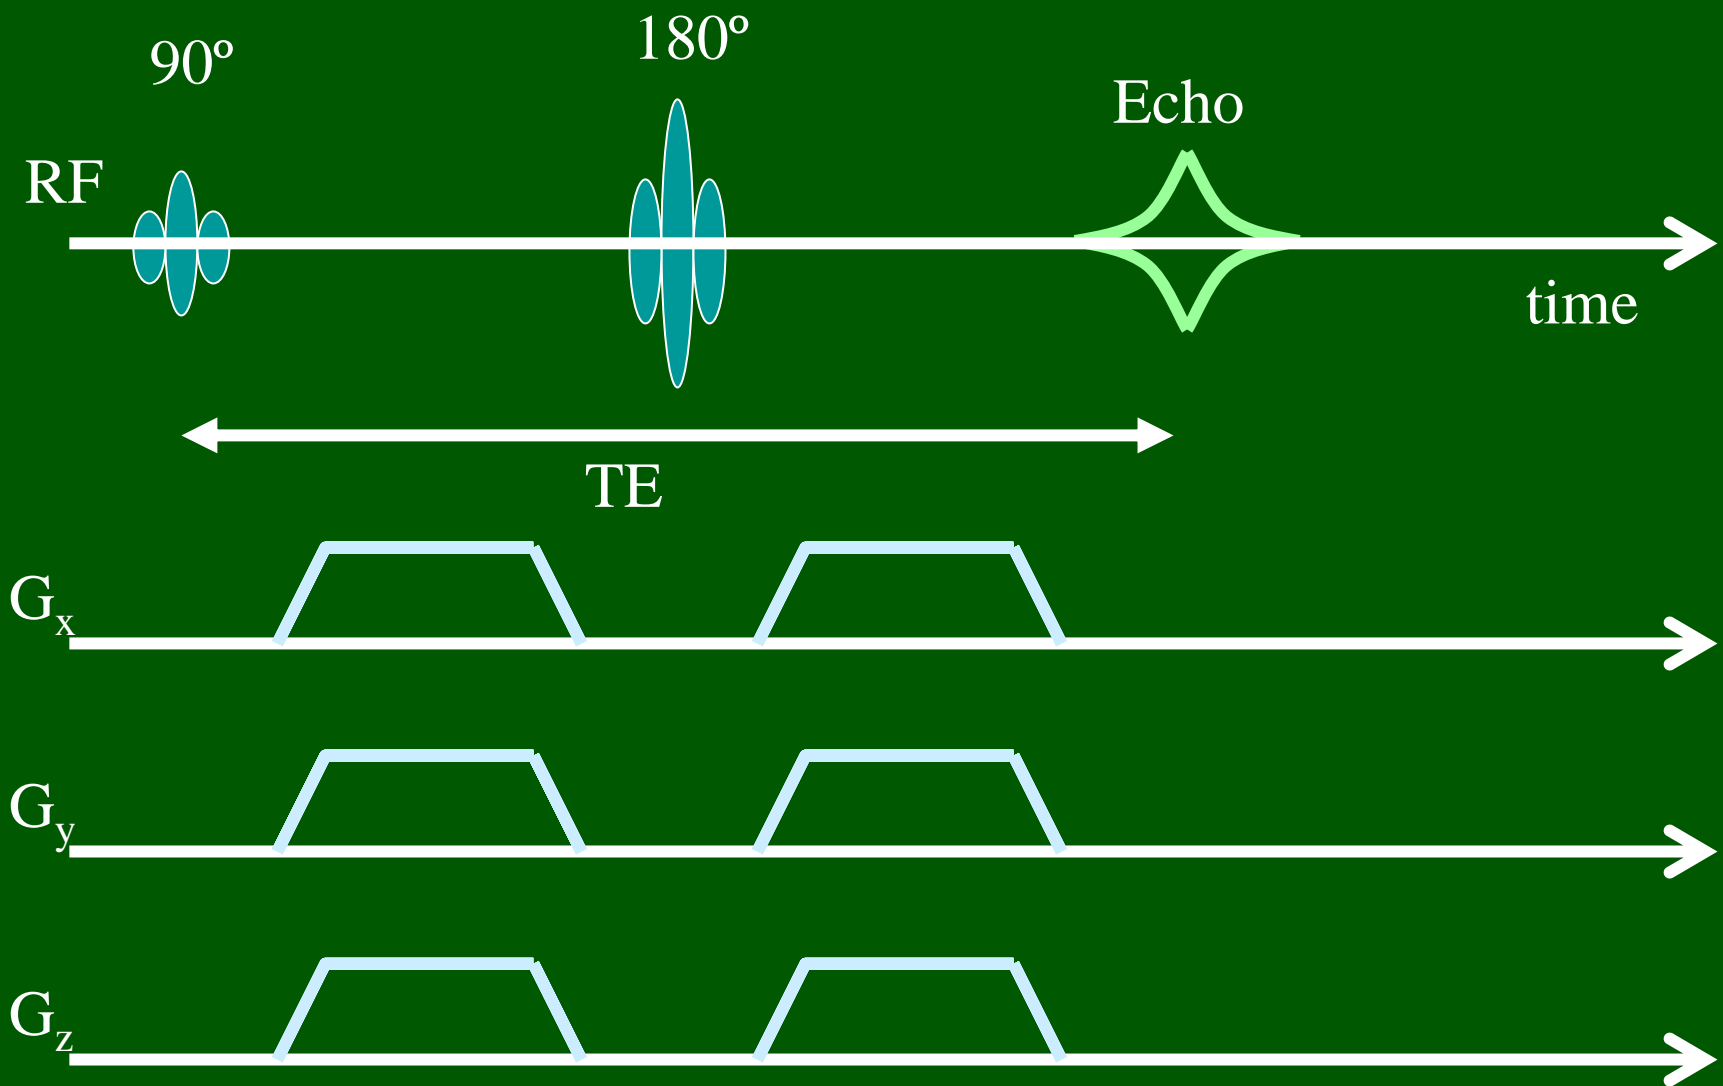

$$b = 1000 \text{ s/mm}^2,$$

$$D = 0.003 \text{ mm}^2/\text{s in water at } 37^\circ \text{ C:}$$

Signal drops about 95% as compared with the

$b = 0$ (T2-weighted) image

Diffusion tensor imaging

Anisotropic attenuation

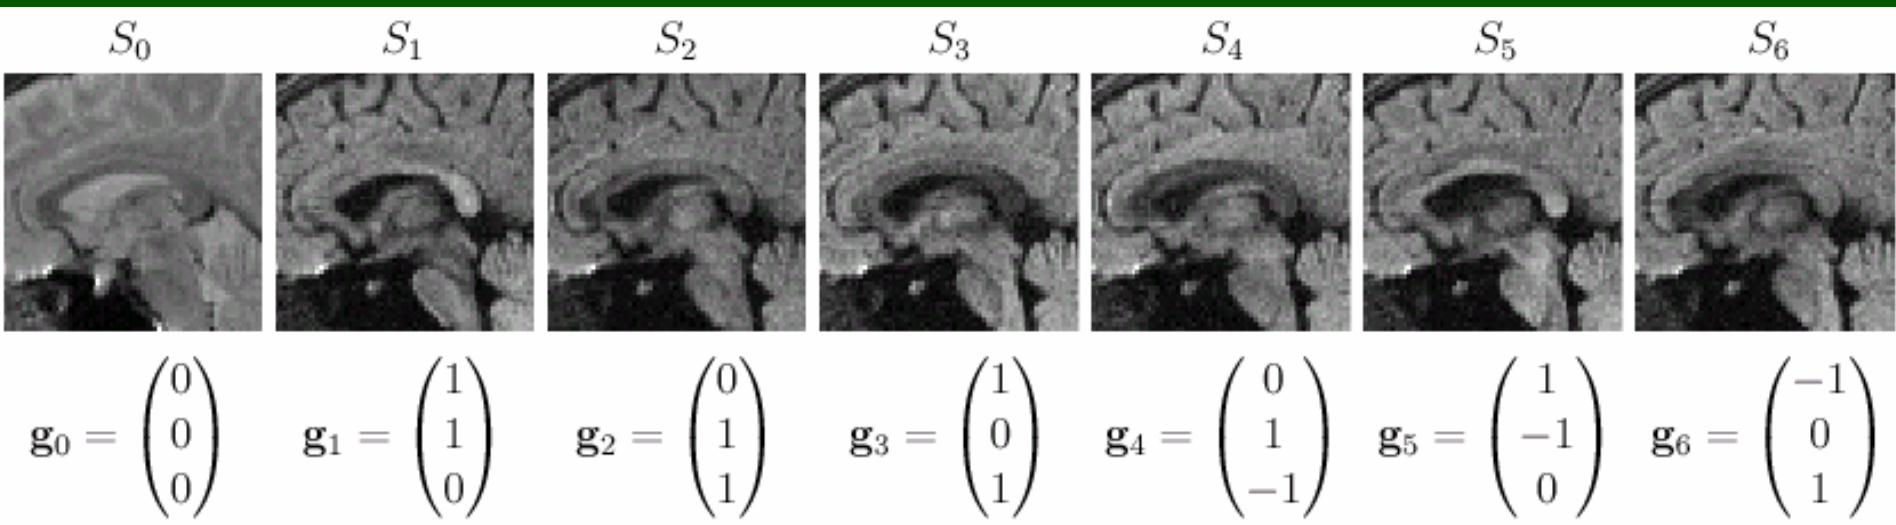

➤ Remember: One dimensional lumped parameter model: $S = S_0 \exp(-bD)$

➤ Now: Directionality dependence

$$S = S_0 \exp(-b \mathbf{g}^t D \mathbf{g}),$$

where \mathbf{g} is a vector containing the diffusion gradient direction,

and D is the diffusion *tensor*

The diffusion tensor

$$D = \begin{pmatrix} D_{xx} & D_{xy} & D_{xz} \\ D_{yx} & D_{yy} & D_{yz} \\ D_{zx} & D_{zy} & D_{zz} \end{pmatrix} = \mathbf{E}^T$$

Tensor derived from
directional diffusivities
(ADC's)

$$\begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & \lambda_3 \end{pmatrix} \mathbf{E}$$

Eigenvalues

Matrix of 3
eigenvectors

What is measured?

Restricted, permeable barrier, hindered diffusion?

How many measurements?

- One needs to measure the symmetric diffusion tensor and a $b=0$ weighted image
- $6+1=7$ measurements
- It has been shown that more = better: 6 icosahedral directions are not rotationally invariant (precision matrix contains 15 indep. parameters and depends on tensor itself)

Fiber orientation mapping

Some invariants (not depending on angle of coordinate system):

$$\text{Mean diffusivity} = \text{tr}(D)/3 = (D_{xx} + D_{yy} + D_{zz})/3$$

Fractional anisotropy =

$$\left[\frac{3\{(\lambda_1 - \Lambda)^2 + (\lambda_2 - \Lambda)^2 + (\lambda_3 - \Lambda)^2\}}{2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2)} \right]^{1/2}$$

with $\Lambda = (\lambda_1 + \lambda_2 + \lambda_3)/3$

Interpreting Diffusivity and FA

Diffusivity and FA help determine the **number**, **size** and **myelination** of fibers, whereas only FA gives information about **directionality**.

Number of fibers

High Diffusivity
Low FA

High FA
Low Diffusivity

Myelination of fibers

High Diffusivity
Low FA

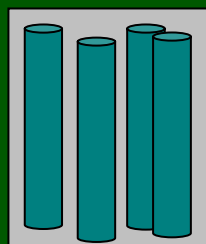

High FA
Low Diffusivity

Size of fibers

High Diffusivity
Low FA

High FA
Low Diffusivity

Directionality of Fibers

Low FA
Same Diffusivity

High FA
Same Diffusivity

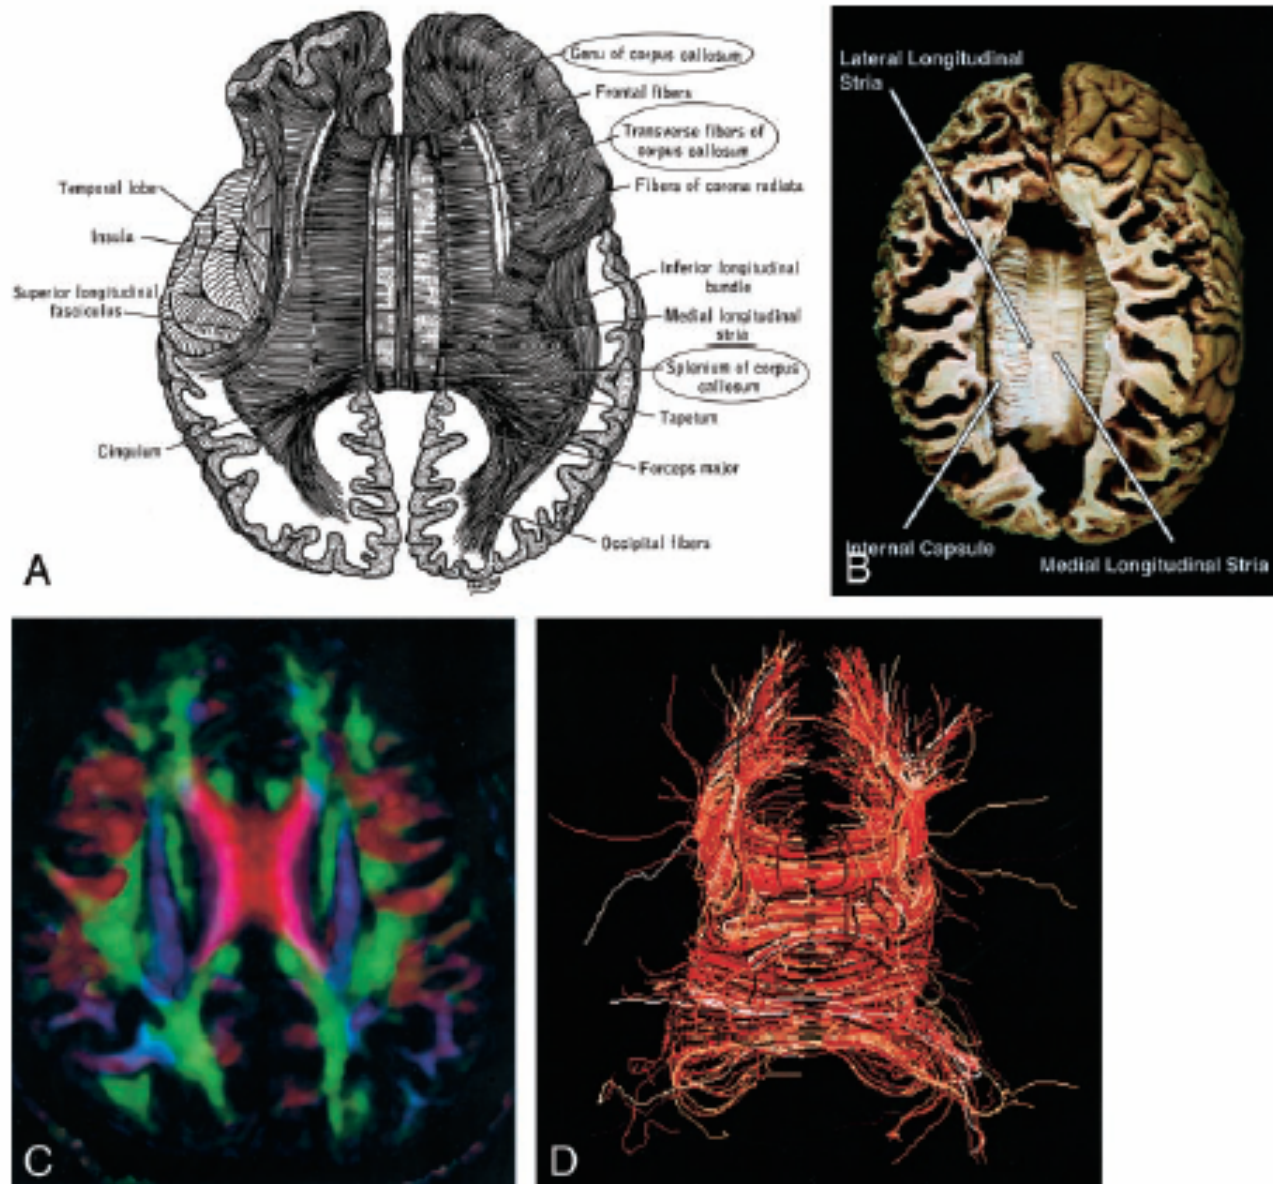

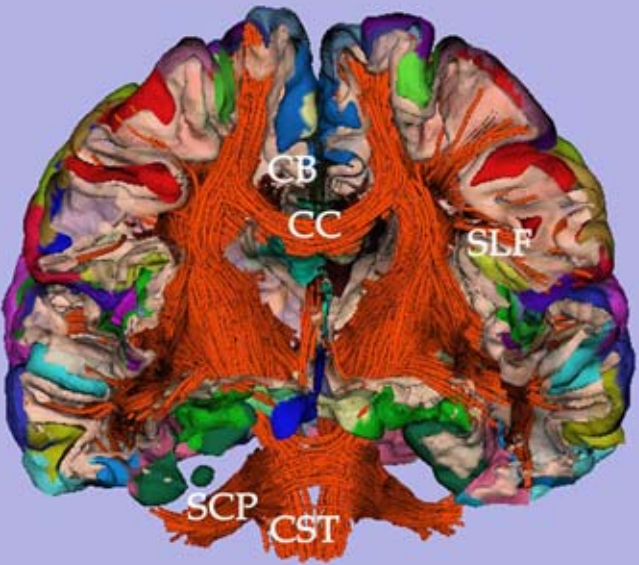

FIG 14. Corpus callosum, axial view.

A–D, Illustration (A), gross dissection (B), directional map (C), and tractogram (D). The largest WM fiber bundle, the corpus callosum connects corresponding areas of cortex between the hemispheres. Close to the midline, its fibers are primarily left-right oriented, resulting in its red appearance on this DTI map. However, callosal fibers fan out more laterally and intermingle with projection and association tracts, resulting in more complex color patterns.

Applications at WMC

- Presurgical planning in epilepsy/tumor patients (Neurosurgery / Radiology)
- Quantification of white matter lesions in traumatic brain injury (Brain Trauma Foundation / Sackler Institute for Developmental Psychobiology)
- Case studies with the Department of Neurology and Neuroscience

Presurgical planning

Neurosurgery/Radiology at NYPH (tumor & epileptic surgery) and CBIC

Patient with tumor infiltrating brain tissue,
block design rhyming paradigm,
ca 100 repetitions a 2s, $0.63 < R < 0.73$, overlaid
onto anatomical image

Fiber tracking in inferior brain regions and cervical spine

Geometric distortions

$$y_+ = y + \Delta y$$

Phase direction

$$y_- = y - \Delta y$$

Intensity distortions

$$\int_0^{y_+} I_+(y_+) dy_+ = \int_0^{y_-} I_-(y_-) dy_-$$

Correction:

Acquire both gradient directions and merge images

Geometry: $y = (y_+ + y_-) / 2$

Intensity: $I = 2I_+I_- / (I_+ + I_-)$

Fiber crossings and non-Gaussian diffusion

q-space imaging

Resolves intravoxel orientational heterogeneity
(crossing / branching / kissing fibers)

- Remember:

$$S = S_0 \int dz_1 P(z_1) \int \exp(i\gamma\delta G(z_2 - z_1)) P(z_2, z_1, \Delta) dz_2$$

- Define $q = \gamma\delta G$ and $z = z_2 - z_1$ to get

$$S(q, \Delta) = S_0 \int \exp(iqz) P(z, \Delta) dz$$

- Therefore, the signal S is again the Fourier-transform of a density P
- By inversion, one can measure P .
- This requires lots of q -values, i.e., one needs to vary timing δ or gradient strength G .

Q-ball imaging

- Drastically reduced scan time
- HARDI-sequence (High angular resolution diffusion imaging)
- Spherically sampled data
- Postprocessing (Funk Radon transform)

The orientation distribution function (ODF)

$$P(\mathbf{r}) = F[S(\mathbf{q})] \quad (\mathbf{r} \text{ and } \mathbf{q} \text{ are reciprocal vectors})$$

$$\text{ODF:} \quad \psi(\mathbf{u}) = \frac{1}{Z} \int_0^\infty P(r\mathbf{u}) dr$$

Q-Ball imaging: Sample only on a sphere, not on 3D volume:

Funk-Radon transform

= extension of planar Radon transform to the sphere

= transform from sphere to sphere

= line integral along equator of sphere, for each vector on sphere

\mathbf{w} = unit direction vector

$f(\mathbf{w})$ = scalar function on sphere

\mathbf{u} = direction of interest

$$G[f(\mathbf{w})](\mathbf{u}) = \int f(\mathbf{w})\delta(\mathbf{w}'\mathbf{u})d\mathbf{w}$$

Extended FRT: Maps from 3D Cartesian space to sphere

\mathbf{x} = unit direction vector

r = particular radius at which FRT is evaluated

$f(\mathbf{x})$ = scalar function in 3D Cartesian space

$$G_r = G[f(\mathbf{w})](\mathbf{u}, r) = \int f(\mathbf{x}) \delta(\mathbf{x}'\mathbf{u}) \delta(|\mathbf{x}| - r) d\mathbf{x}$$

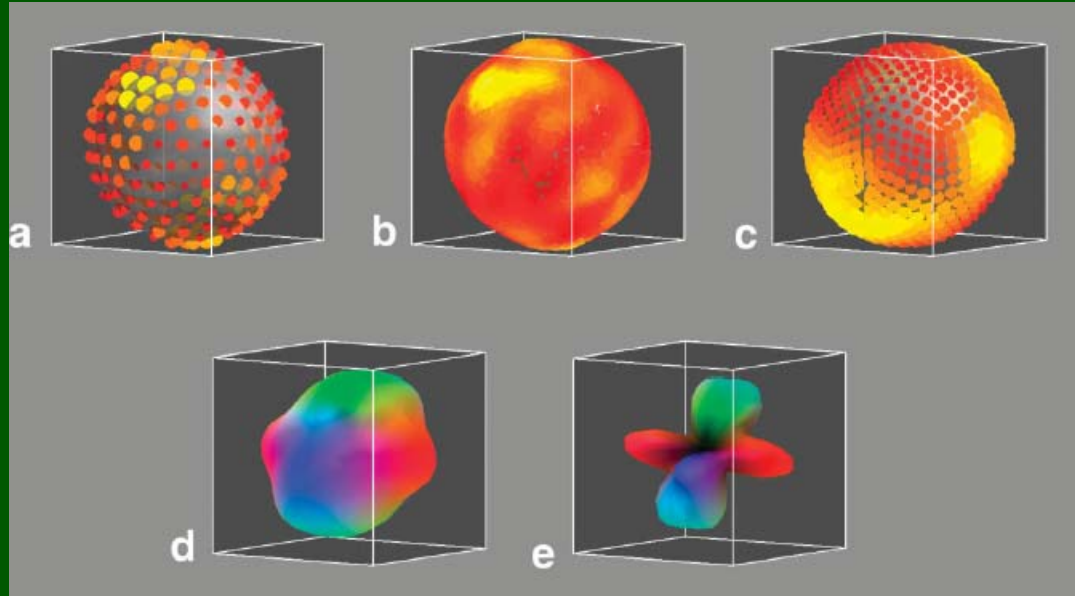

Theorem (D. S. Tuch):

The extended FRT of the diffusion signal gives a strong approximation to the ODF, i.e.,

$$\psi(\mathbf{u}) \approx \frac{1}{Z} G_r[S(\mathbf{q})] \quad (\mathbf{u} \text{ and } \mathbf{q} \text{ are reciprocal vectors})$$

The sum of the diffusion signal over an equator approximately gives the diffusion probability in the direction normal to the plane of the equator.

Central element: The diffusion orientation distribution function (ODF)

- (a) Diffusion signal sampled on fivefold tessellated icosahedron ($m = 252$). The signal intensity is indicated by the size and color (white yellow red) of the dots on the sphere.
- (b) Regridding of diffusion signal onto set of equators around vertices of fivefold tessellated dodecahedron.
- (c) Diffusion ODF calculated using FRT.
- (d) Color-coded spherical polar plot rendering of ODF.
- (e) Min-max normalized ODF.

(D. S. Tuch 2004)

ODF map of caudal midbrain

cp, cerebral peduncle;
ctt, central tegmental tract;
fp, frontopontine tract;
rst, reticulospinal tract;
scp, superior cerebellar peduncle;
sn, substantia nigra;
xscp, crossing of the superior cerebellar peduncle.

Mathematical/statistical problems

- How to reduce # of measurements?
- How to smooth tensor fields? (bias-variance optimum?)
- Can one learn more about tissue properties than fiber directions from ODF?
- Global fiber tracking algorithms?
- Do proper bootstrapping?
